

SYNTHESIS, CHARACTERIZATION AND OPTIMIZATION OF CERIUM AND
CALCIUM OXIDES BASED CATALYSTS TOWARDS CARBON DIOXIDE
METHANATION REACTION

MALIK MUHAMMAD ASIF IQBAL

A thesis submitted in fulfilment of the
requirements for the award of the degree of
Doctor of Philosophy

Faculty of Science
Universiti Teknologi Malaysia

MARCH 2020

DEDICATION

This thesis is dedicated to the most honourable personality of the whole universe to **Muhammad (SALLALLAHOU ALAYHE WASALLAM)**.

ACKNOWLEDGEMENT

All praises to almighty Allah, who created the universe and knows whatever is in it, hidden or evident, and who bestowed upon me the intellectual ability and wisdom to search for its secrets.

I am very pleased to express my sincere gratitude to my ever-affectionate advisor Dr. Susilawati Toemen, and my co-advisors, Prof. Dr. Wan Azelee Wan Abu Bakar, Dr. Nur Izyan Wan Azelee, and Dr. Fazira Ilyana Abdul Razak for introducing me to the wonders and frustrations of scientific research. I thank my advisors for their guidance, encouragement, and support in developing this work. It was only thanks to her leadership that my efforts were successful. Special thanks go to the members of the Wan Azelee group, including Dr. Salmiah Jamal Mat Rosid, Dr. Renugambaal Nadarajan, Dr. Nur Fatin Sulaiman, Dr. Nur Afiqah Badli, Dr. Norhasyimah Mohd Kamal, Mr. Ashiru Abubakar Garba and Mrs. Nashwa Mohammed Alahmar, for their discussions during my research. The staff of the Faculty of Science supported the highest quality, and especially I would like to thank Mr. Amin.

I would like to express my eternal gratitude to my parents for their everlasting love and support. There are not enough words to express my humble obligation for my affectionate sister for her sacred prayers and gracious behavior. Last but not the least, I would like to thank my wife, without her moral support, I cannot enroll myself in PhD.

Malik Muhammad Asif Iqbal

ABSTRACT

Novel trimetal-oxide (Ru/Fe/Ce) supported on γ -Al₂O₃ catalysts were synthesized by simple impregnation method. The conversion of CO₂ to CH₄ was optimized using response surface methodology (RSM) based on the amount of catalyst loading, calcination temperatures and catalyst dosages. In addition, stability, reliability, robustness, reproducibility, and regeneration testing were also investigated. Superior catalytic performance was obtained using catalyst with ruthenium content of 5 wt% loading, iron content of 10 wt% loading and cerium content of 85 wt% loading which was calcined at 1000°C for 5 h. The CO₂ conversion achieved 97.2% at 275°C with CH₄ formation of 93.5%. The Ru/Fe/Ce (5:10:85)/ γ -Al₂O₃ catalyst exhibits excellent catalytic stability up to 65 h. CO₂-TPD results revealed this catalyst possesses medium-strength basic sites while TPR study revealed the catalyst exhibits best reduction pre-treatment at >250°C. Meanwhile, the BET analysis illustrated the catalyst possesses a mesoporous structure. XRD revealed the transformation of cubic Al₂O₃ calcined at 1000°C to rhombohedral at 1100°C. TEM micrographs revealed the d-spacing value is in accordance with XRD analyses. FESEM micrographs displayed the catalyst surface is covered with small, dispersed spherical particles. EDX mapping profile showed good distributions of Ce, Fe, and Ru on the catalyst surface. The physicochemical analyses have shown that the active sites of the potential catalyst Ru/Fe/Ce (5:10:85)/ γ -Al₂O₃ are RuO₂ (t), Fe₂O₃ (r), Al₂O₃ (c), Al₂O₃ (r) and CeO₂ (c) with a particle size <10 nm. The mechanistic studies have shown that CO₂ methanation occurs via the adsorption of CO₂ on surface of ceria and iron oxide, and then stepwise hydrogenation leading to CH₄ formation through carboxylate intermediate by the hydrogen spilled over from Ru surface. As a result, dissociated hydrogen over ruthenium reacts with surface carbon, leading to formation of *CH intermediate, which subsequently hydrogenated to produce *CH₂, *CH₃ and finally to the desired product methane. The Ru/Fe/Ca (5:25:70)/ γ -Al₂O₃ catalyst calcined at 1000°C gave a maximum conversion of 85.59% CO₂ with CH₄ formation of 79.58% at a reaction temperature of 300°C which was less as compared to the potential catalyst Ru/Fe/Ce (5:10:85)/ γ -Al₂O₃.

ABSTRAK

Mangkin baharu trilogram-oksida (Ru/Fe/Ce) yang disokong pada γ -Al₂O₃ telah disintesis melalui kaedah pengisitepuan mudah. Penukaran CO₂ kepada CH₄ telah dioptimumkan menggunakan kaedah permukaan gerak balas (RSM) berdasarkan jumlah muatan mangkin, suhu pengkalsinan dan dos mangkin. Tambahan lagi, ujian kestabilan, kebolehpercayaan, keteguhan, kebolehlungan dan penjanaaan semula telah juga dikaji. Prestasi pemangkinan unggul diperolehi menggunakan mangkin dengan kandungan rutenium 5 wt%, muatan kandungan ferum 10 wt%, dan muatan kandungan serium 85 wt% yang dikalsinkan pada 1000°C selama 5 j. Penukaran CO₂ mencapai 97.2% pada 275°C dengan pembentukan CH₄ 93.5%. Mangkin Ru/Fe/Ce (5:10:85)/ γ -Al₂O₃ mempamerkan kestabilan pemangkinan yang sangat baik sehingga 65 j. Keputusan CO₂-TPD mendedahkan mangkin ini mempunyai tapak bes berkekuatan sederhana manakala kajian TPR mendedahkan mangkin ini mempamerkan pengurangan pra-rawatan terbaik pada >250°C. Sementara itu, analisis BET menunjukkan mangkin mempunyai struktur mesoporos. XRD mendedahkan transformasi Al₂O₃ kubik dikalsinkan pada 1000°C kepada rombohedral pada 1100°C. Mikrograf TEM mendedahkan nilai d-jarak adalah bersesuaian dengan analisis XRD. Mikrograf FESEM memaparkan permukaan mangkin ditutupi dengan zarah-zarah kecil berbentuk sfera yang tersebar. Profil pemetaan EDX menunjukkan penyebaran yang baik bagi Ce, Fe, dan Ru pada permukaan mangkin. Analisis fisikokimia menunjukkan bahawa tapak aktif bagi mangkin yang berpotensi Ru/Fe/Ce (5:10:85)/ γ -Al₂O₃ adalah RuO₂ (t), Fe₂O₃ (r), Al₂O₃ (c), Al₂O₃ (r) CeO₂ (c) dengan saiz zarah <10 nm. Kajian mekanistik menunjukkan bahawa metanasi CO₂ terjadi melalui penjerapan CO₂ pada permukaan seria dan ferum, dan kemudian penghidrogenan langkah demi langkah membawa kepada pembentukan CH₄ melalui perantaraan karboksilat oleh hidrogen yang terbebas dari permukaan Ru. Akibatnya, hidrogen yang terpisah pada rutenium bertindak balas dengan permukaan karbon, yang membawa kepada pembentukan perantaraan *CH dan penghidrogenan selanjutnya menghasilkan *CH₂, *CH₃ dan akhirnya produk metana yang dikehendaki. Mangkin Ru/Fe/Ca (5:25:70)/ γ -Al₂O₃ yang dikalsin pada 1000°C memberi penukaran maksimum, 85.59% CO₂ dengan pembentukan CH₄ 79.58% pada suhu tindak balas 300°C yang mana ia lebih rendah berbanding dengan mangkin berpotensi Ru/Fe/Ce (5:10:85)/ γ -Al₂O₃.

INTRODUCTION

1.1 Background

Anaerobic decomposition of non-fossil organic material produces natural gas. This highly flammable gas is a homogenous liquid with low density and viscosity. Moreover, acidic gases such as CO₂ and H₂S are also present in the natural gas (Curry, 1981). Malaysia has been extracting sour natural gas. Before the purification process begins, Malaysian natural gas consists of several gaseous impurities (Bakar and Ali, 2010). The chemical composition of crude Malaysian natural gas is shown in Table 1.1

Table 1.1 Chemical composition of crude natural gas, Terengganu, Malaysia (Bakar and Ali, 2010).

Chemical Name	Chemical formula	Percentage (%)
Methane	CH ₄	40-50
Ethane	CH ₃ -CH ₃	5-10
Propane	CH ₃ -CH ₂ -CH ₃	1-5
Carbon dioxide	CO ₂	3-20
Hydrogen sulphide	H ₂ S	0-1

To increase the calorific value of natural gas and prevent corrosion of pipelines and process equipment, it is essential to eliminate the presence of CO₂ in raw natural gas. Moreover, at a very low temperature, CO₂ tends to freeze to form solidified CO₂,

which leads to clogging of the pipeline. This impurity in natural gas can reduce its quality and thus reduces the market price of gas. Therefore, the elimination of carbon dioxide from the natural gas is very important to prevent or minimize the emission of hazardous gases into the environment. Among the multiple human activities that produce GHGs, the usage of energy is undoubtedly the largest source as shown in Figure 1.1.

Figure 1.1 Shares of global anthropogenic GHGs emission (Quadrelli and Peterson, 2007).

1.2 Various technologies for the CO₂ removal from natural gas

At present, there are many ways to capture and separate CO₂. Three general categories of processes available for removal of CO₂ from refinery gas streams are chemical solvents, physical solvents, and solid adsorbents (Maples, 2000).

1.2.1 Chemical absorption method

Alkanolamine includes the family of organic compounds such as monoethanolamine (MEA), diglycol amine (DGA), diisopropanol amine (DIPA), methyl diethanolamine (MDEA), diethanolamine (DEA) and triethanolamine (TEA). Among these amines, MEA is the strongest because it can remove both CO₂ and H₂S from the gas streams. In the chemical absorption process, typically amine solution such as MEA

is employed and its recovery rate for CO₂ is 98%. The MEA solution absorption process has been used commercially in the gas industry for 60 years and is considered the most mature process (Mokhatab *et al.*, 2018). However, this method can only work if CO₂ is present not more than 10%.

1.2.2 Physical adsorption method

Adsorption process is generally considered as low energy intensive and very cost-effective method. Physical adsorbents such as zeolites, molecular sieves, polymers, templated silicas, and activated carbon typically adsorb water vapor better over CO₂ and their CO₂ adsorption capacity at low pressure is not sufficiently high (Bell *et al.*, 2010; Olajire, 2010). However, the main drawback of this process is the high amount of adsorbent required due to large amount of flue gases in stationary plants.

1.2.3 Membrane technology

The quality of natural gas can also be improved with special polymer membranes. These membranes can reduce the concentration of H₂S and CO₂, but they are not as effective for the separation of toxic gases and require high cost (Omidvar *et al.*, 2019). This method uses polymeric membranes (contains semi-permeable elements), which are responsible for the separation of gas constituents by selective permeation in contact with the membrane. A two-stage membrane system is considered better than a single-stage hydrocarbons recovery system. Moreover, the system is highly effective at low flow rates, but its performance is reduced when the flow rate exceeds the set limit. Thus, this method is economically ineffective as the flow rate increases (Kohl and Riesenfeld, 1997). UOP polymeric membranes are more effective for the removal of H₂S from natural gas, although natural gas has higher concentration of H₂S and higher operating pressures. These membranes cut off acidic gases to a reduction level from 70-90% (Cnop *et al.*, 2007). However, polymeric

membranes have drawbacks like low permeability and selectivity, plasticization at high temperatures, but also insufficient thermal and chemical stability.

1.3 Catalytic methanation

Methanation of CO₂ is an important process for the purification of natural gas. Hydrogen gas is used in addition to the carbon dioxide gas to form methane (CH₄). The methanation process is shown in the equation below.

The advantage of catalytic methanation has led researchers to choose this process due to its higher thermal stability, good chemical resistance to solvents, high mechanical strength, recyclable and long lifetime.

Our previous studies (Bakar *et al.*, 2015; Rosid *et al.*, 2019; Toemen *et al.*, 2016; Toemen *et al.*, 2018; Zamani *et al.*, 2014) has drew attention on methanation reaction, which highlights that how adsorption strength of CO₂ is controlled by Lewis basicity of catalyst, and the charge transfer from metal surface to chemisorbed CO₂. Different transition metals and lanthanide elements such as Ni, Pd, Rh, Cu, Mn, Ru and Ce supported on alumina were investigated. Zamani *et al.* (2014) has reported the methanation of carbon dioxide over Ru/Mn/Cu(10:30:60)/Al₂O₃ catalyst calcined at 1035°C could give 98.5% CO₂ conversion and 70% methane (CH₄) formation at reaction temperature of 220 °C. The use of high loading makes it more economical, and it shows less formation of methane as well as showed stability for seven hours only that makes it unfit to use it in industrial application. In another study by Bakar *et al.* (2015), the Ru/Mn/Ni(5:35:60)/Al₂O₃ catalyst calcined at 1000°C showed excellent methanation catalytic activity. They reported the potential catalyst exhibited the highest catalytic activity at a reaction temperature of 400°C, which gave 99.74% of CO₂ conversion with a low yield of 72.36% of methane. The Ru/Mn/Ni (5:35:60)/Al₂O₃ catalyst calcined at 1000°C showed reproducibility for several times

and also shows good stability and no deactivation for up to 100 h. However, a high reaction temperature of 400°C and low yield of 72.36% are the main drawbacks of this catalyst.

The CO₂ conversion using neodymium doped with manganese and ruthenium was studied by Rosid *et al.* (2019). They evaluated that Ru/Mn/Nd (5:20:75)/Al₂O₃ calcined at 1000°C gave CO₂ conversion of 100% and CH₄ formation of 40.0% at a reaction temperature of 400°C under molar ratio of 4:1 (H₂:CO₂). This result suggested that a lot of formation of by products along with the methane and higher reaction temperature makes it unfit to use at industrial level. Ceria is a well-known oxygen storage material, able to store and release in a reversible manner large amounts of oxygen was used by Toemen *et al.* (2018) for the production of SNG from CO₂ hydrogenation. The ceria based catalyst impregnated with Ru/Mn/Al₂O₃ was developed. The experimental results have shown that Ru/Mn/Ce (5:30:65)/Al₂O₃ catalyst calcined at 1000°C achieved 97.73% of CO₂ conversion with 91.31% of CH₄ at a reaction temperature of 200°C. The catalyst started to deactivate (spent catalyst) at 6th cycle with a CO₂ conversion of 41.17%. This catalyst also faces a problem in terms of low stability.

1.4 Role of metal oxides in methanation reaction

1.4.1 Role of ceria in methanation reaction

In many catalytic reactions, CeO₂ is an active component because it can absorb and release oxygen by transformation between Ce⁴⁺ and Ce³⁺ (Zhou *et al.*, 2016). The bulk vacancies created in CeO₂ catalyst after reduction at high temperature could enhance the carbon dioxide methanation (Trovarelli *et al.*, 1995). Due to its high basicity, CO₂ is easily adsorbed on CeO₂ catalyst that could contribute to high CO₂ conversion (Tada *et al.*, 2014).

1.4.2 Role of calcium oxide in methanation reaction

CaO is widely used as an excellent promoter for various catalysts owing to its high CO₂ chemisorption capacity (Sengupta and Deo, 2015). It has been identified that CaO is good adsorbing material for CO₂ because of its low cost, natural abundance and stoichiometric reactive sorption capacity of 0.785(g of CO₂/g of oxide) which is higher than other metal oxide such as BaO has 0.287 (g of CO₂/g of oxide), K₂O has 0.468 (g of CO₂/g of oxide), SrO has 0.425 (g of CO₂/g of oxide), ZnO has 0.540 (g of CO₂/g of oxide) (Feng *et al.*, 2007).

1.4.3 Role of iron oxide in methanation reaction

The lower iron content was characterized by the highest selectivity with respect to CH₄ while the catalyst with the highest Fe content had the lowest methane selectivity. The increase in iron content resulted in a decrease in both carbon dioxide conversion and methane production (Kang *et al.*, 2011). Iron oxide is responsible for the elongation and bending of linear structure molecule of CO₂ to facilitate the lower reaction temperature of methanation (Jo *et al.*, 2000).

1.4.4 Role of ruthenium oxide in methanation

Ruthenium is the most active metals for CO₂ methanation (Wang *et al.*, 2016). Ru cluster size also affects the product selectivity during CO₂ reduction with H₂. With increasing particle size, Ru increase selectivity with respect to methane formation and decreases the production of carbon monoxide (Kwak *et al.*, 2013). High activity, low load and long-time stability are vital factors leading to the use of Ru in the methanation reaction. Ru is an excellent noble metal for breaking H₂ gases into H atoms on the surface of the catalyst.

1.5 Response Surface Methodology (RSM)

Response surface methodology (RSM) is a set of statistical and mathematical methods beneficial for the development, improvement, and optimization of processes. In recent years, RSM is the common most used for optimization methods. The experimental design and statistical analysis are carried out using the Design-Expert software. The development of experiments is now of importance due to their significant advantages, such as the reduction of the number of experiments, the minimization of operating costs and time, as well as the improvement of the analysis of the results obtained. RSM is a powerful statistical and mathematical analysis method that is used to extend, develop, and modify the catalytic optimization process through numerous studies (Toemen *et al.*, 2014). To assess the impact of process variables and their interaction on the response to achieve optimal conditions, Box-Behnken design (BBD) was used in this research.

1.6 Problem Statement

Carbon dioxide is one of the major natural gas impurities by its composition of 20-30%. The CO₂ presence leads to the environmental pollution as well as the natural gas delivery system. The emitted CO₂ into the atmosphere contributes to global warming. At the same time, the presence of CO₂ can cause corrosion in main pipelines. The delivery pipeline is generally blocked by freezing, resulting in various maintenance problems and reduced production efficiency. Hence, it is necessary to completely remove hazardous CO₂ gas in natural gas. Several technologies like chemical absorption method, physical absorption method and membrane technology are used in the natural gas sweating process. But these methods are still not effective, have a low selectivity and are not economically efficient. They can remove only 10% of CO₂ in the crude natural gas. Green technology can be applied to remove CO₂ by a catalytic methanation reaction. CO₂ can be converted to methane gas so that methane production can be increased.

The previous studies have shown that methanation catalysts such as cobalt, nickel, manganese, copper and zinc deposited on alumina support face challenges in terms of stability, reproducibility, regeneration, and operating temperature catalysts. Therefore, the development of a highly active catalysts is an important goal aiming the production of methane at low temperatures and high conversions of CO₂. Problems have been revealed with rapid deactivation of methane catalysts in reaction conditions and low selectivity with respect to desirable products such as methane.

1.7 Research Objectives

The main purpose of this study is to develop potential catalysts that can operate effectively at very low possible temperature for CO₂ methanation reaction. The main objectives of this study are:

1. To synthesize, characterize and optimize the catalytic activity of alumina supported CeO₂ and CaO based bi- and tri-metallic catalysts using Fe₂O₃ and RuO₂ for the hydrogenation of CO₂ to methane.
2. To verify the optimal conditions attained in laboratory experiments by comparing its results with the predicted value of RSM.
3. To investigate the reproducibility, regeneration, and stability of the potential catalyst.
4. To propose the methanation reaction mechanism over potential catalyst.

1.8 Scope of study

The aim of this study is to prepare cerium and calcium-oxides based catalysts for CO₂ methanation reaction. The catalysts were prepared by incipient wetness impregnation method and supported on γ -Al₂O₃. The incorporation of iron and ruthenium as co-catalysts was added in order to enhance the catalytic methanation.

The prepared catalysts were calcined at 400°C, 700°C and 1000°C and was tested in home built microreactor connected to FTIR.

In order to determine the optimal conditions for catalysts that contribute to the highest CO₂ conversion, several optimization parameters such as calcination temperatures, co-catalyst loadings, catalyst dosages, reliability testing, reproducibility testing and stability testing were studied. Catalytic optimization validation was executed using the statistical method of response surface methodology (RSM). Various analytical methods such as Nitrogen Adsorption method (NA), Thermogravimetry Analysis-Differential Thermal Analysis (TGA-DTA), X-rays Diffraction (XRD), Field Emission Scanning Electron Microscope-Energy Dispersive Analysis of X-Ray (FESEM-EDX), Transmission Electron Microscopy (TEM) and X-ray Photoelectron Spectroscopy (XPS) were used to study the physical properties of the catalysts. Adsorption properties of CO₂ depending on the reaction temperature were studied using IR analysis.

1.9 Significance of study

The present study is of interest from the perspective of the concept that CO₂ present in natural gas can be used to produce valuable methane without the loss of undesired component (CO₂). The methanation process can be used to process a large quantity of CO₂ in a short time. The catalysts developed were effective at low temperature, stable, moderately basic in nature and resistant to chemicals. This “green technology” approached for the production of methane gas was considered as an environmentally friendly method for waste to wealth concept. This green technology helps to reduce problems associated with acid rain, ozone depletion or greenhouse effect, and to improve the quality of natural gas. Catalysts developed in this study have contributed not only to economic growth, but also to the creation of a green environment. Furthermore, the catalysts were easy to prepare, environmentally friendly, stable, reusable and used at low reaction temperatures.
