PROCESS IMPROVEMENT AND ENERGY SAVING MEASURES FOR
SEWAGE TREATMENT PLANT

MOHD NORFADHLI BIN MUSTAFA KAMAL

A project report submitted in fulfilment of the
requirements for the award of the degree of
Master of Philosophy

Faculty of Chemical and Energy Engineering
Universiti Teknologi Malaysia

FEBRUARY 2023

ACKNOWLEDGEMENT

Alhamdulillah, praise be to Allah the Al-Mighty. I wish to express my gratitude to my supervisor, Assoc. Prof. Dr. Zarina Bt Ab Muis for her strong support, constant comments, suggestion, guidance, and encouragement throughout this work.

I would like to express my sincere thanks to my wife, my parent, family, in-law and friends for their infinite support, love, patience and understanding throughout my entire education. The love and support that they have shown me throughout my life has been incredible, and they have always had the wisdom to know when I still needed a helping hand.

I am also indebted to Universiti Teknologi Malaysia (UTM) for the facilities and environment for this hybrid online and physical of study. My gratitude for SIRIM Berhad as my employer for sponsored me to pursue this postgraduate level and hoping that this will be not the last.

For all of that, I am very thankful to the co-operation and contribution from everyone that has driven me to accomplish of this project. There is no such meaningful word then. May Allah Bless you all

ABSTRACT

Energy in sewage treatment plant (STP) show the differential energy consumption on various stages which it depends on the indicator of the findings. To do comparison and benchmarking, the suitable key energy consumption indicator need to identify, and the suitable method need to formulate in performing the energy. This study is to perform energy saving measures (ESM) and process improvement for the STP. The study started with planning to select the STP and study on the potential of method to use. Sites visit then conducted to make an overall overview of STP and the related data was collected to do analysis. The propose ESM and process improvement analyzed in term of results feasibility, findings, and economic analysis. Introducing the Solar PV systems by do comparison type of panel and area available will determine the potential of savings. Retrofitting the lighting for existing 36W fluorescent to LED T8 14W and for 300W spotlight to 150W LED spotlight also help the STP to reduce the energy consumption. Retrofitting the Sequencing Batch Reactor (SBR) to produce biogas and the development of Combine Heat and Power (CHP) plant to generate electricity will reduce the demand of electricity from the grid. The waste heat produced later can be used for sludge dewatering process. Sludge utilization will help the STP to generate yearly income rather than allocate budget for the sludge removal from the STP. The overall result which is categorized according to the options will the analyzed to perform the best selected option. The best option is to utilize all the available potential area of Solar PV installation along with another ESM and utilization to obtain the best result. The combination of proposed improvement being analyzed according to the selected option, economic feasibility, energy savings, CO₂ reduction and simple payback period with expected reducing the energy consumption and cost at the STP. As conclusion, the implementation of all the propose ESM and utilization will lead the savings in many aspects of area to the STP.

ABSTRAK

Tenaga di loji rawatan kumbahan menunjukkan perbezaan pada pelbagai peringkat yang mana ianya bergantung kepada penunjuk aras penggunaan tenaga. Untuk membuat perbandingan dan penanda aras, penunjuk aras penggunaan tenaga yang utama hendaklah dikenalpasti dan kaedah yang sesuai hendaklah digunakan untuk merumuskan penggunaan keseluruhan tenaga. Kajian ini adalah untuk mencadangkan langkah penjimatan tenaga (ESM) dan penambahbaikan kepada proses pada loji kumbahan ini. Kajian bermula dengan merancang untuk memilih loji kumbahan dan kaedah yang sesuai untuk digunakan. Lawatan tapak telah dijalankan untuk mendapatkan gambaran keseluruhan berkaitan loji kumbahan dan pengambilan data yang diperlukan juga direkodkan untuk analisa lanjut. Cadangan langkah penjimatan dan penambahbaikan proses dianalisa meliputi skop kebolehlaksanaan, jumpaan analisis dan juga analisa dari sudut ekonomi. Sistem solar PV dicadangkan dengan membuat perbandingan pada jenis panel yang digunakan dan juga mengenalpasti kawasan yang berpotensi untuk dibangunkan sistem ini. Pengubahsuaian ke atas sistem lampu sediaada dengan menukar lampu jenis 36W pendarflor kepada jenis LED T8 14W dan lampu tumpu sediaada 300W kepada jenis LED 150W dapat membantu kepada pengurangan tenaga di loji ini. Pengubahsuaian ke atas tangki *Sequencing Batch Reactor* (SBR) adalah untuk penghasilan biogas dan pembangunan loji *Combine Heat and Power* (CHP) adalah untuk penjanaan elektrik dan dapat mengurangkan kebergantungan kepada grid. Haba yang dijana boleh digunakan untuk proses penyahairan enapcemar. Penggunaan optimum enapcemar dapat membantu loji untuk mengurangkan kos pengurusan sediaada dengan menjual enapcemar yang terhasil untuk proses lain dan dapat menjana pendapatan kepada loji. Keputusan kajian secara keseluruhan dibahagikan mengikut pilihan dan analisa dijalankan untuk menentukan pilihan terbaik yang mana adalah dengan menggabungkan semua langkah penjimatan yang dicadangkan. Kombinasi pilihan dianalisa mengikut kategori pilihan, kebolehlaksanaan, penjimatan tenaga, pengurangan CO₂ dan tempoh bayaran balik dengan jangkaan pengurangan penggunaan tenaga dan penjimatan kos kepada loji. Kesimpulannya pelaksanaan semua langkah penjimatan akan menghasilkan penjimatan dari sudut pelbagai aspek pada loji rawatan kumbahan ini.

CHAPTER 1

INTRODUCTION

1.1 Research Background

Climate change has become a global concern over the decade and resulted aggressive commitments in energy integration to reduce greenhouse gas (GHG) emission. There are variety of effect on life on the planet due to climatic variation. The available technologies and emissions reduction options shall include to reach net-zero emission by 2050. By 2030, low-emission energy sources expected to rise to 50% as shown in below:

Figure 1.1 Low Emission Energy Supplies Sources Displaces Unabated Fossil Fuel by 2030 (IEA,2021)

Sewage treatment is the process of converting sewage into bilge water that can be discharged back to environment to prevent wasted. It is a facility with combination of processes that are used to treat the sewage and remove pollutant. It contains of high amount of chemical, hydrodynamic, and thermal energy that have potentially exploited for several uses. Sewage treatment plant (STP) are consuming high electricity consumption and it has locally potential to produces renewable energy by having high potential for heat generation, capability to produce biogas in the anaerobic digestion (AD) process. The overall process of the STP as shown in figure below:

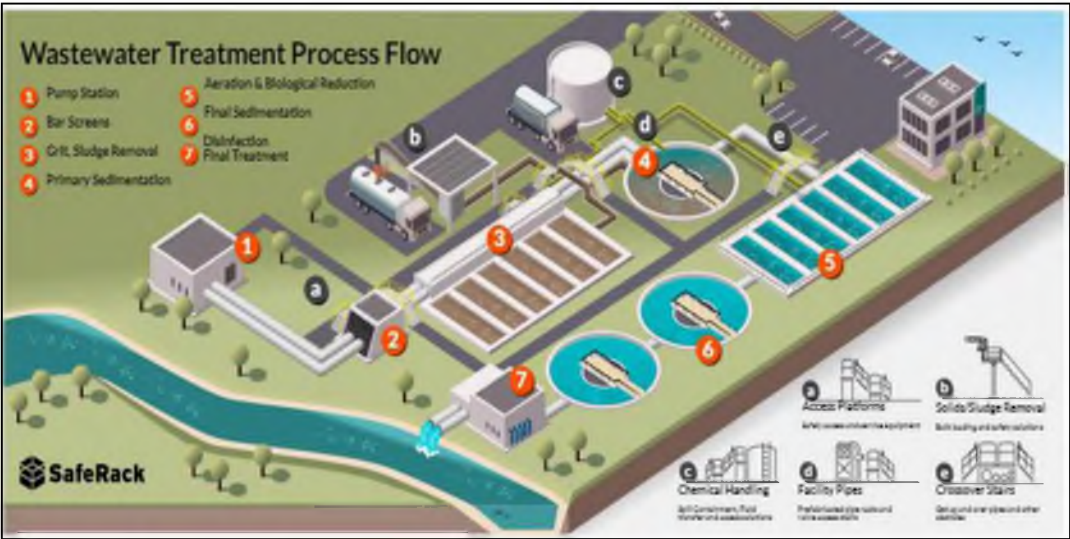

Figure 1.2 STP Process Flow Overview

STP energy consumption in a standard STP reported with mean value of 0.25-0.33 kWh/m³ (Pietro Elia, 2021) mainly consumed during the aeration process estimated 60% from total energy consumption. The pumping process estimated 13% of energy consumption while the sludge treatment contributes of 15% energy usage. Figure below shows the percentages of the energy consumption in standard or common STP.

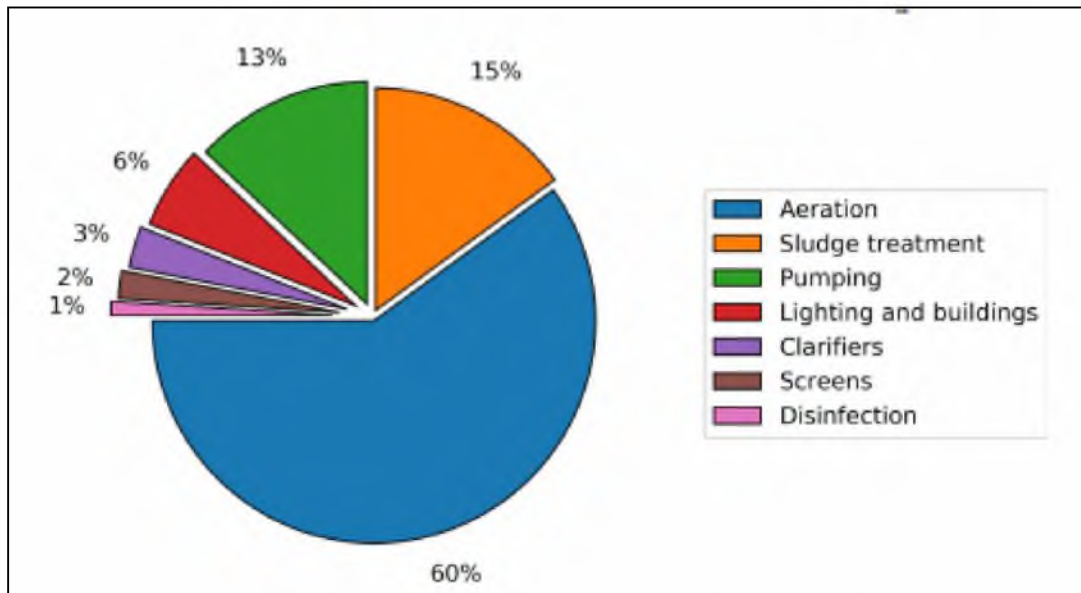

Figure 1.3 Energy Consumption in Standard STP

1.2 Problem Statement

Rapid urbanization and industrial growth for last 50 years have brought high standard of living, exhaustion of resources, loss of biodiversity, degradation of environment, pollution, and the threat of climatic agitation through greenhouse effect. The demand of treating STP led to development the number of processes in order to allow to minimize the pollution and to ensure the maximum or large quantities of water to be recirculated for various purpose. There is the surge of electricity demand when installation of new STP, increasing the cost for development and increase the energy demand. In other words, it will contribute to the high carbon emission directly. This study focusing on the sewage treatment plant at the residential area.

The STP result in large amount of indirect carbon dioxide emission by consuming a lot of power during the process. There is typical energy conservation and emission reduction technology available in the market in order to reduce the energy such as photovoltaic power generation, and sludge anaerobic digestion technology with a biogas cogeneration system.

Potential energy saving and process improvement with suitable methodology is important to identifying the suitable key energy consumption indicators for benchmarking and to compare with different STP. Current used treatment method is more to removing potential energy rather than recovered the energy for the potential of use even though there are 10 times amount of potential energy as the energy used to treat the sewage (Ele Greenberg,CEM). The economic, energy and carbon neutral analysis were established in order to propose the most potential improvement measures that can be apply in the STP.

1.3 Research Objective

The main purpose of the research is to evaluate the STP process and to propose the energy improvement measures and to optimizing the overall process of the STP. The objective that has been identified to attend as follows: -

- To analyze the profile for the STP process and proposed process improvement
- To propose the energy saving measures (ESM)
- To perform economic analysis for STP for all proposed improvement measured or method

1.4 Research Scopes

The research scope shall include:

- Perform literature review on the STP process and energy usage
- Carry out the improvement measured and the method to optimizing the overall process.
- Analyze the optimal improvement and solution in term of technical, commercial, and environmental aspects.

1.5 Significance of the study

Aeration process in the STP consumed the highest electricity consumption. Optimizing the overall process of the STP will lead to reducing energy consumption from the grid and contribute to reducing GHG emission. Installation of solar PV and re-used other waste to perform renewable energy is important to reduce electricity consumption from the grid. It will reduce fossil fuel consumption and ultimately mitigate the effects of climate change and global warming.

Sludge and gas produce from the STP also being re used back by doing analysis and process to produce as RE. Installation of solar PV is the best option to reducing electricity demand from the grid along with other ESM proposed in this research.

Hence, this study is to provide the energy saving measures, proposed the RE, and optimizing the overall STP. The feasibility study also being conduct and review.
