

HARNESSING ENERGY FROM MICRO VIBRATION USING SMART  
MATERIALS

AMEIRUL AZRAIE BIN MUSTADZA

A project report submitted in partial fulfillment of the  
requirements for the award of the degree of  
Master of Engineering (Mechanical)

Faculty of Mechanical Engineering  
Universiti Teknologi Malaysia

JANUARY 2012

To my beloved wife, **Fara Fatihah** who believes in me even though I find it difficult to do so myself, my adorable daughter **Puteh 'Arissa**, who gives me strength to complete this thesis and my parents, **Mustadza** and **Noorfah** who always believe in me and guide me in all my pursuits.

## ACKNOWLEDGEMENT

First and foremost, the author would like to thank Allah, the Most Beneficent and the Most Merciful for His blessings throughout the process of completing this project.

The author would like to express his deepest appreciation to his project supervisor, Assoc. Prof. Dr. Intan Zaurah Binti Mat Darus for all the advice, guidance, support and encouragement throughout this project and in the preparation of this thesis.

The author would like to extend his appreciation to his beloved wife Fara Fatihah Binti Ibrahim, father Mustadza Bin Md. Yusop, mother Noorfah Binti Senusi and his family for their support and encouragement which has indeed inspired the author to complete this project.

Lastly, the author would like to thank all his colleagues who have contributed in one way or another, directly or indirectly in the process of carrying out this project.

## ABSTRACT

Energy harnessing for the purpose of powering low power electronic devices has received much attention in the last few years. By harnessing ambient energy from the environment it will eliminate the need for batteries and supplying the portable electronic devices such as cell phones, laptops and MP3 players with infinite amount of energy. The ambient energy that can be harnessed to generate electricity comes from a wide range of sources but vibration energy shows a promising amount of power generation. In this study, conversion of mechanical vibration into electricity using piezoelectric vibration-to-electricity converter is undertaken with a focus to quantify the amount of power that can be generated and identify electronic devices that can fully utilize this power. The study is divided into two main parts which are simulation from the forced vibration data and laboratory experiment on vibrating mechanical equipments such as turbine and centrifugal pump. The simulation result shows that as the acceleration magnitude increases, the average direct voltage also increases from 4.5 mV to 8.1 mV and the average power output that could be harnessed also increases from 22.5  $\mu$ W to 40.5  $\mu$ W. Similarly, the experimental result shows that for the turbine, as the speed of the turbine increases from 1150 rpm to 1450 rpm, the average power produced increases from 1.63  $\mu$ W to 2.02  $\mu$ W. Also, for the centrifugal pump, as the speed increases from 1700 rpm to 1900 rpm, the average power produced increases from 3.02  $\mu$ W to 3.06  $\mu$ W. The experimental results also revealed that within 30 minutes, 1.84  $\mu$ W of energy could be harnessed from the vibration of the turbine at speed of 1450 rpm while 3.06  $\mu$ W of energy could be harnessed from the vibration of the centrifugal pump at speed of 1900 rpm. This power output is sufficient for low-powered wireless sensor networks in silent mode which can be used in variety of applications as indicated in the previous literatures.

## ABSTRAK

Pengembangan tenaga bagi tujuan membekalkan kuasa kepada peranti elektronik kuasa rendah telah mendapat perhatian sejak beberapa tahun kebelakangan ini. Dengan memanfaatkan tenaga ambien dari persekitaran, ia akan dapat mengurangkan kebergantungan kepada bateri dan membekalkan alat-alat elektronik mudah alih seperti telefon bimbit, komputer riba dan pemain MP3 dengan jumlah tenaga yang tidak terbatas. Tenaga ambien yang boleh dimanfaatkan untuk menjana tenaga elektrik datang dari pelbagai sumber tetapi tenaga getaran menunjukkan potensi jumlah penjanaan kuasa. Dalam kajian ini, penukaran getaran mekanikal kepada tenaga elektrik yang menggunakan piezoelektrik penukar getaran-kepada-elektrik dilaksanakan dengan fokus untuk mengira jumlah kuasa yang boleh dijana dan mengenal pasti peranti elektronik yang boleh menggunakan kuasa ini sepenuhnya. Kajian ini terbahagi kepada dua bahagian utama iaitu simulasi dari data getaran paksa dan eksperimen makmal ke atas peralatan mekanikal yang bergetar seperti turbin dan pam empar. Keputusan simulasi menunjukkan bahawa dengan kenaikan magnitud pecutan, voltan langsung purata juga meningkat daripada 4.5 mV kepada 8.1 mV dan kuasa purata yang boleh dimanfaatkan juga meningkat daripada 22.5  $\mu\text{W}$  kepada 40.5  $\mu\text{W}$ . Begitu juga, hasil eksperimen menunjukkan bahawa untuk turbin, apabila kelajuan turbin meningkat dari 1150 rpm ke 1450 rpm, kuasa purata yang dihasilkan meningkat dari 1.63  $\mu\text{W}$  ke 2.02  $\mu\text{W}$ . Di samping itu, untuk pam empar, apabila kelajuan meningkat dari 1700 rpm ke 1900 rpm, kuasa purata yang dihasilkan meningkat dari 3.02  $\mu\text{W}$  ke 3.06  $\mu\text{W}$ . Keputusan eksperimen juga mendedahkan bahawa dalam tempoh 30 minit, 1.84  $\mu\text{W}$  tenaga boleh dimanfaatkan dari getaran turbin pada kelajuan 1450 rpm manakala 3.06  $\mu\text{W}$  tenaga boleh dimanfaatkan dari getaran pam empar pada kelajuan 1900 rpm. Kuasa ini adalah mencukupi untuk rangkaian sensor tanpa wayar berkuasa rendah dalam mod senyap yang boleh digunakan dalam pelbagai aplikasi seperti yang dinyatakan dalam penulisan kajian terdahulu.

## LIST OF SYMBOLS

|                    |   |  |
|--------------------|---|--|
| $^{\circ}\text{C}$ | - | Celsius  |
| $\Phi_B$           | - | Magnetic flux  |
| $\Omega$           | - | Ohm  |
| $\delta$           | - | Mechanical strain  |
| $\varepsilon$      | - | Induced emf; Dielectric constant                                 |
| $\varepsilon_0$    | - | Dielectric constant of free space, Permittivity of free space    |
| $\mu_0$            | - | Permeability of free space                                       |
| $\sigma$           | - | Mechanical stress  |
| $\sigma_y$         | - | Yield stress   |
| A                  | - | Ampere   |
| $a$                | - | Acceleration   |
| $B$                | - | Magnetic field   |
| $C$                | - | Capacitance  |
| $c$                | - | Elastic constant   |
| $D$                | - | Electrical displacement (charge density)                         |
| $d$                | - | Gap or distance between plates; Piezoelectric strain coefficient |
| dB                 | - | Decibel  |
| $E$                | - | Electric field   |
| $f$                | - | Frequency  |
| Hz                 | - | Hertz  |
| $I, i$             | - | Current  |
| $k$                | - | Coupling coefficient; Piezoelectric constant                     |
| $l$                | - | Length of one coil ( $2\pi r$ ); Length of plate                 |
| m                  | - | Meter  |
| $N$                | - | Number of turns in coil  |
| $Q$                | - | Charge on capacitor  |
| $R$                | - | Resistance   |

|                        |   |  |
|------------------------|---|--|
| rpm                    | - | Revolution per minute                      |
| <i>s</i> , sec         | - | Second                                     |
| <i>t</i>               | - | Thickness                                  |
| <i>V</i> , <i>Volt</i> | - | Voltage                                    |
| $V_p$                  | - | Voltage peak                               |
| $V_{pp}$               | - | Voltage peak-to-peak                       |
| W                      | - | Watt                                       |
| <i>w</i>               | - | Width of plate                             |
| <i>Y</i>               | - | Modulus of elasticity (Young's Modulus)    |
| <i>y</i>               | - | Distance coil moves through magnetic field |

## CHAPTER 1

### INTRODUCTION

#### 1.1 Introduction

Over the last 20 years, the continuous development of technology has significantly reduced the size and increased the function of electronic devices and in parallel decreased their power consumption (Gonzalez *et al.*, 2002). Nowadays hand held and portable electronic devices such as cell phones, laptops and MP3 players provide users with comprehensive functions which include communication, computing and audio functions. Batteries are commonly used to power the electronic devices. However, due to its limited capacity, batteries could possibly supply power only for short lifetime of about one to three years and its significant size and weight has caused problem to the present hand held and portable devices. This problem has then led to the rising demand for self-powered electronic devices because the usage of current battery technology to power electronic devices has become impractical.

The advancement of current technology has helped to fulfill the demand for self-powered electronics devices by harnessing ambient energy from the environment, thus eliminating the need for batteries and supplying these electronic devices with infinite amount of energy. The ambient energy that can be harnessed to generate electricity is coming from a wide range of sources such as human body (Shenck and Paradiso, 2001; Starner, 1996) and temperature gradient (Stordeur and Stark, 1997).

Another form of energy sources that has received attention from researchers for energy harnessing is vibration (Chiu and Tseng, 2008; Glynne-Jones *et al.*, 2004; Lefeuvre *et al.*, 2006; Roundy and Wright, 2004; Roundy *et al.*, 2002; Roundy *et al.*, 2003; Williams *et al.*, 2001; Williams and Yates, 1996; Yen and Lang, 2006) which can be observed in buildings, factories, vehicles, industrial machineries and household appliances. Typically, vibration energy can be converted into electric energy by three methods, namely electromagnetic (inductive) (Glynne-Jones *et al.*, 2004; Williams *et al.*, 2001; Williams and Yates, 1996), electrostatic (capacitive) (Chiu and Tseng, 2008; Roundy *et al.*, 2002; Yen and Lang, 2006) and piezoelectric conversion (Lefeuvre *et al.*, 2006; Roundy and Wright, 2004; Roundy *et al.*, 2003). Table 1.1 shows a comparison of potential energy sources with a fixed level of power generation and a fixed amount of energy storage where all power density values are normalized to the size of  $1 \text{ cm}^3$  based on the size of typical wireless sensor nodes (Rabaey *et al.*, 2002).

Table 1.1: Comparison of potential energy sources with a fixed level of power generation and a fixed amount of energy storage

| Sources                                | Power Density<br>( $\mu\text{W}/\text{cm}^3$ )<br>1 year lifetime | Power Density<br>( $\mu\text{W}/\text{cm}^3$ )<br>10 year lifetime |
|--|---|--|
|  | Solar (outdoors)  | 15,000 – direct sun<br>150 – cloudy day                            |
| Solar (indoors)                        | 6 – office desk   | 6 – office desk  |
| Shoe inserts                           | 330   | 330  |
| Temperature gradient                   | 15 at $10^\circ\text{C}$ gradient                                 | 15 at $10^\circ\text{C}$ gradient                                  |
| Vibration (electromagnetic conversion) | 100   | 100  |
| Vibration (electrostatic conversion)   | 50  | 50   |
| Vibration (piezoelectric conversion)   | 200   | 200  |
| Batteries (non-rechargeable lithium)   | 45  | 3.5  |
| Batteries (rechargeable lithium)       | 7   | 0  |
| Hydrocarbon fuel (micro heat engine)   | 333   | 33   |
| Fuel cells                             | 280   | 28   |

The driving force to harness ambient energy from the environment is mostly due to the development of wireless sensor and actuator networks where particular research has been conducted for a project named PicoRadios (Rabaey *et al.*, 2002). This project aims to develop a small and flexible wireless platform for ubiquitous wireless data acquisition that minimizes power dissipation. The important specifications for the power system developed by PicoRadios project researchers are the total size and average power dissipation of an individual node. The size of a node must not be larger than  $1 \text{ cm}^3$  and the target average power dissipation of a completed node is  $100 \text{ }\mu\text{W}$ .

The previous research also showed a promising amount of power density about  $50$  to  $200 \text{ }\mu\text{W}/\text{cm}^3$  that can be harnessed from vibration energy as illustrates in Table 1.1. Therefore, the measure of acceptability of an energy harnessing solution will be its ability to provide  $100 \text{ }\mu\text{W}$  of power in less than  $1\text{cm}^3$ . However, this does not mean that solutions which do not meet this criterion are not worthy of further exploration but simply that they will not meet the needs of the PicoRadios project. Thus, the primary criterion to evaluate power sources in this research is power per volume with a target of at least  $100 \text{ }\mu\text{W}/\text{cm}^3$ .

## 1.2 Problem Statement

Batteries are type of energy storage devices that commonly used to power hand held and portable electronic devices as well as implanted biomedical systems. However, due to its limited capacity, batteries could possibly supply power only for short lifetime of about one to three years and its significant size and weight has caused problem to the present hand held and portable devices as well as implanted biomedical systems. While researchers continuously developed the technology to increase the energy of storage devices, the solutions are still going to have finite lifetime. This problem has led to the rising demand for self-powered devices and systems which can be solved by harnessing energy from a wide range of sources using a few technique that have been proven can supply infinite amount of power. In this study, conversion of mechanical vibration into electricity using piezoelectric

material is undertaken with a focus to quantify the amount of power that can be generated and identify electronic devices that can fully utilize this power.

### **1.3 Objectives**

The objective of this project is:

1. To design, simulate and develop an instrumentation system to harness energy from micro vibration using smart materials.

### **1.4 Scopes**

The scopes of this project are:

1. To conduct a research on the sources of vibration, methodologies and devices of harnessing energy and its applications.
2. To design and simulate the instrumentation system to harness energy from vibration and to propose a methodology to store the energy.
3. To develop and fabricate the instrumentation system to harness energy from vibration using piezoelectric, rectifier and energy storage.
4. To verify and validate thus developed instrumentation system with an actual source of vibration from vibrating mechanical equipments.

### **1.5 Research Methodology**

The methodologies involved in this study are shown in Figure 1.1. The project starts by collecting reading materials such as books, journals and technical papers specifically on sources of vibration, methods of converting ambient vibration energy into electrical energy, types of piezoelectric material, piezoelectric energy harnessing circuit and types of energy storage.

Research has been done continuously throughout this study to get a better understanding on the concept of harnessing energy from ambient vibration using piezoelectric material. Besides, consultation sessions with the project supervisor and few colleagues who are doing similar research were also held periodically to discuss any arising issues and problems encountered pertaining to this study.

Based on the research conducted, piezoelectric energy harnessing circuit selection process was made in order to get the suitable circuit followed by the selection of a few types of energy storage devices to be used in this study. The study on piezoelectric energy harnessing has been divided into two main parts which are (1) simulation of the vibration environment and (2) laboratory experiment on vibrating mechanical equipments. Both simulation and laboratory experiment will undergo the same process such as piezoelectric vibration to electricity conversion, rectification and energy storage.

The simulation in Matlab SIMULINK has been done using vibration data acquired from experimental study by previous researcher in order to determine the possible amount of power density output that can be produced for the specific acceleration input. With the promising amount of power density output produced during simulation, the laboratory experiment on vibrating mechanical equipments was conducted for the purpose of quantifying the amount of power that can be generated by vibrating mechanical equipments and identifying electronic devices that can fully utilize this power.
