A thesis submitted in fulfillment of the
requirements for the award of the degree of
Masters of Engineering (Bioprocess)

Faculty of Chemical Engineering
Universiti Teknologi Malaysia

JANUARY 2012

To my beloved mother and father

ACKNOWLEDGEMENT

In preparing this thesis, I was in contact with many people, researchers, academicians and industrial practitioners who have contributed greatly to my understanding and thoughts. In particular, I would like to take this opportunity to express my gratitude to my supervisor, Professor Dr. Hesham A. El-Enshasy for his encouragement, guidance, critics and friendship. I am also very thankful to the research officers at the Institute of Bioprocess Development (IBD) namely Puan Norzalina Othman and Cik Roslinda Malek for their guidance, advice and encouragement. Without their continued support and interest, this thesis would not have been the same as presented here.

I am also indebted to All Cosmos Industries Sdn. Bhd. for funding my Masters study. Technicians and research assistants of IBD also deserve special thanks for their assistance in the execution of numerous experiments. My fellow postgraduate and undergraduate students should also be recognized for their continuous support. My sincere appreciation also extends to all my colleagues and others who have provided assistance at various occasions. Their ideas and views are useful indeed. Unfortunately, it is not possible to list all of them in this limited space. I would once again like to express my sincerest gratitude to my family members and all who have contributed to the completion of this thesis.

ABSTRACT

Azotobacter vinelandii is a free-living N-fixing bacterium capable of converting atmospheric nitrogen into ammonia, a nitrogen source easily assimilated by plants. Although numerous researches have been done on the genetics and metabolism of *A. vinelandii*, little information on cell mass production for biofertilizer applications is available. Therefore, the objective of this research is to develop an industrial culture medium and a cultivation strategy for the mass production of *A. vinelandii* in a semi-industrial scale. Based on previous works, several media formulations were tested for their cell growth potential. The best medium yielded a cell mass of only 3.94 g L⁻¹ in shake flask cultures and was optimized using both a classical and statistical approach, achieving a maximum cell mass of 7.71 g L⁻¹ and 8.82 g L⁻¹, respectively. The cell yield on glucose of the classically optimized medium was approximately 35.5% higher than the statistically optimized medium and was thus used in subsequent bioreactor experiments. Batch cultivations in 16-L stirred tank bioreactors with and without pH control yielded cell mass concentrations of 7.52 g L⁻¹ and 15.86 g L⁻¹ respectively. A series of fed-batch cultivations was carried out to determine the factors limiting cell growth. A combination of a constant feeding strategy coupled with pH and dissolved oxygen control with additional pure oxygen sparging was found to yield the highest cell mass concentration of 40.65 g L⁻¹ in 16-L bioreactor cultivations. The cultivation in a 150-L stirred tank bioreactor revealed that oxygen is one of the most critical factors affecting cell mass production of the highly aerobic *A. vinelandii*. The decreased oxygen transfer rate limited cell growth but increased alginate production. The maximum cell mass obtained in a fed-batch culture of *Azotobacter vinelandii* in a 150-L stirred tank bioreactor was 28.35 g L⁻¹ while the maximum alginate concentration was 18.60 g L⁻¹.

ABSTRAK

Azotobacter vinelandii merupakan sejenis bakteria pengikat-N yang boleh menukarkan nitrogen di atmosfera kepada ammonia yang boleh diserap oleh tumbuhan. Walaupun banyak kajian telah dijalankan ke atas genetik dan metabolisme bakteria ini, namun maklumat tentang strategi pengkulturan ketumpatan sel tinggi untuk pengaplikasian bio-baja masih kekurangan. Oleh itu, objektif utama kajian ini adalah untuk menghasilkan mediakultur dan strategi yang sesuai untuk pengkulturan ketumpatan sel tinggi *A. vinelandii*. Berdasarkan kajian yang lepas, beberapa mediakultur telah dipilih untuk diuji kesesuaiannya untuk pengkulturan *A. vinelandii*. Media terbaik memberi ketumpatan sel sebanyak 3.94 g L^{-1} dalam pengkulturan di dalam kelalang kon. Pengoptimuman komposisi media dijalankan atas media ini menggunakan kaedah klasik dan statistik. Ketumpatan sel yang diperoleh dari media optimum klasik dan statistik setiap satunya adalah 7.71 g L^{-1} dan 8.82 g L^{-1} . Media optimum klasik yang menunjukkan hasil sel yang lebih tinggi (35.5%) dipilih untuk pengkulturan seterusnya dalam bioreaktor 16-L. Pengkulturan berkelompok di dalam bioreaktor 16-L dengan dan tanpa kawalan pH masing-masing menghasilkan 7.52 g L^{-1} dan 15.86 g L^{-1} sel. Satu siri pengkulturan suap kelompok dijalankan untuk menentukan faktor-faktor yang mempengaruhi pertumbuhan sel. Kombinasi pengkulturan suap kelompok dengan aliran nutrien malar, kawalan pH dan oksigen dengan aliran gas oksigen tulen menghasilkan ketumpatan sel tertinggi, 40.65 g L^{-1} dalam bioreaktor 16-L. Pengkulturan *A. vinelandii* dalam bioreaktor 150-L menghasilkan ketumpatan sel sebanyak 28.35 g L^{-1} dan alginat adalah 18.60 g L^{-1} . Ini menunjukkan bahawa oksigen merupakan salah satu faktor utama yang mempengaruhi pertumbuhan sel di mana penurunan kadar pemindahan oksigen meningkatkan penghasilan alginat berbanding dengan penghasilan sel.

CHAPTER I

INTRODUCTION

1.1. Background

Food security is one of the most important global issues affecting the world today. In 2007, the Food and Agriculture Organization of the United Nations, (FAO) estimated that the number of chronically hungry people in the world rise by 75 million to reach a total of 923 million. Current food insecurity will be further aggravated by the increasing world population. The FAO estimates that the global population will reach approximately 8 billion in 2025 and around 9 billion in 2050 before stabilizing at slightly more than 10 billion after 2100. Even before the world population stabilizes, world food production must increase by more than 75 percent to feed the entire world population by 2025 (FAO). Since little new land is suitable for crop production, the output per unit area must increase to meet increasing food demand (Mosier et al., 2004; Bumb and Baanante, 1996).

Efforts to increase the productivity of crops have seen a tremendous increase in fertilizer usage over the years. FAO estimates the world fertilizer consumption to grow annually at about 1.7 percent from 2007/2008 to 2011/12. This growth is equivalent to an increment of about 15 million tonnes and is expected to reach a total demand of 180 million tonnes by 2030. Although chemical fertilizers are able to supply crops with the necessary nutrients for greater yield and productivity, their excessive use may lead to numerous health hazards and detrimental effects to the environment. For instance, the excessive use of nitrogen, N fertilizers may lead various implications such as nitrate leaching which could result in the pollution of water systems (Fisher and Newton, 2002), emission of greenhouse gases such as nitrogen oxides (NO, N₂O) and volatilization of ammonia (Roy *et al.*, 2006; Mosier *et al.*, 2004; Hernandez, 2002).

Since nitrogen is one of the most vital minerals required by plants, a viable alternative is to supply this element through biological nitrogen fixation, BNF. BNF is a natural process whereby diazotrophs such as *Acetobacter*, *Azoarcus*, *Azotobacter*, *Azospirillum*, *Cyanobacteria*, *Glucoacetobacter*, *Pseudomonas* and *Rhizobium* reduce stable molecular nitrogen from the atmosphere to ammonia which can then be readily available to plants (Newton, 2007; Roy *et al.*, 2006).

Azotobacters are also known to produce a wide range of growth promoting nutrients to plants apart from fixing nitrogen. This not only supplies the necessary nutrients to plants but also helps rejuvenate the soil (Roy *et al.*, 2006). Hence, microbial inoculants or biofertilizers containing diazotrophs like *Azotobacter vinelandii* are seen as viable replacements for detrimental mineral nitrogen fertilizers.

1.2. Problem Statement

Although there is much data on *Azotobacter vinelandii*, most researches are either focused on the genetics and metabolism of the bacteria or alginate production. There is however still little information regarding high cell density cultivation strategies for *Azotobacter vinelandii*. On the contrary, most cultivation media are designed to favor the production of alginate over biomass. Therefore, there is a need to develop an industrial medium and high cell density cultivation strategy to maximize cell mass production while minimizing alginate formation. Conditions for optimal alginate production are known to limit cell growth.

1.3. Objective

The main objective of the present work is to develop an industrial medium and cultivation strategy to maximize the biomass production by *Azotobacter vinelandii* NRRL B-14641 with minimal alginate production.

1.4. Scope

- a) Media optimization for high cell mass production of *Azotobacter vinelandii* using classical approach.
- b) Media optimization for high cell mass production of *Azotobacter vinelandii* using statistical approach.
- c) Comparison between classical media optimization approach and statistical media optimization approach.

- d) Batch cultivation of *Azotobacter vinelandii* in a 16-L pilot scale stirred tank bioreactor for high cell mass production.
- e) Fed-batch cultivation of *Azotobacter vinelandii* in a 16-L pilot scale stirred tank bioreactor for high cell mass production.
- f) Scaling-up of cultivation process for *Azotobacter vinelandii* to a 150-L pilot scale stirred tank bioreactor for high cell mass production.
