A project report submitted in partial fulfilment of the
requirements for the award of the degree of
Master of Engineering (Electrical - Electronics & Telecommunications)

Faculty of Electrical Engineering
Universiti Teknologi Malaysia

JUNE 2012

Dedication to my beloved parents and family for their everness support and care

ACKNOWLEDGEMENT

First and foremost, thanks God, for blessing me the strength to complete this research study. I wish to express my gratitude to several people that helped me during the course of my Master's programme at Universiti Teknologi Malaysia.

I would like to acknowledge the Radio Communications Department(RaCed)head, my supervisor Associated Professor Dr. Mohammad Kamal Abdul Rahim who has given me support and guidance throughout the period of this project. His guidance and perseverance towards the aspects of this study enables me to complete this research. Without him this project report will not become a reality.

I am very grateful to my parents, for their endless prayers, love and encouragement, not only during this master's program, but also during all my life. May god protect and guide both of you. I also thank my siblings for their warm support and encouragement during my study life.

Thanks all of you

Ali Khalajmehrabadi

ABSTRACT

Recent advancements in antenna structures have gathered lots of attention toward dielectric resonator antennas (DRAs). Wide impedance bandwidth, low dispersion loss, and high efficiency are the highlighted characteristics that caused DRAs to be the focus point of scholars and industry. Besides, there is a need to have a circular polarized antenna to alleviate the problem of having the same transmitter and receiver orientation. For circular polarization, several designs have been proposed. In order to have a higher axial ratio bandwidth, most of the proposed structures suggest having a two feed mechanism. Although they have a higher CP bandwidth rather than single feeding structures, the complexity in fabrication is a problem. Thus, there is a great need to have structures with a single feeding method and high axial ratio bandwidth. This thesis represents a novel DRA configuration that is excited with a simple micro strip feed line with a truncated ground plane. Thus, the fabrication is simplified via one feeding mechanism. Besides, a square shape notch is created inside the DRA patch and is rotated 45 degrees to create a low axial ratio. Since the whole structure is mounted vertically on the edge of its substrate, the high radiation resulted in a wide matching band width. The proposed compact DRA antenna showed a good radiation characteristic with an impedance bandwidth of 5.9GHz between 3.9GHz and 9.8GHz and axial ratio of 1.25GHz between 3.9GHz and 5.15GHz and axial ratio of 900MHz between 7GHz and 7.9GHz.

ABSTRAK

Kemajuan terkini dalam struktur antenna telah berkumpul banyak perhatian ke arah antenna resonator (DRAs) yang dielektrik. Galangan lebar jalur yang luas, rendah penyebaran, kerugian dan kecekapan yang tinggi adalah ciri-ciri penting yang menyebabkan DRAs menjadi titik tumpuan ulama dan industri. Selain itu, terdapat keperluan untuk mempunyai sekeliling antenna polarisasi untuk mengurangkan masalah yang mempunyai pemancar yang sama dan orientasi penerima. Bagi polarisasi sekeliling, reka bentuk telah dicadangkan. dalam untuk mempunyai jalur lebar nisbah paksi yang lebih tinggi, kebanyakan struktur yang dicadangkan mencadangkan mempunyai mekanisme dua suapan. Walaupun mereka mempunyai CP jalur lebar yang lebih tinggi dan bukannya struktur pemakanan tunggal, kerumitan dalam fabrikasi adalah masalah. Oleh itu, terdapat adalah suatu keperluan yang hebat untuk mempunyai struktur dengan kaedah suapan satu dan nisbah paksi tinggi jalur lebar. Tesis ini mewakili tatarajah DRA novel yang teruja dengan mudah jalur mikro suapan selaras dengan satah tanah yang terpotong. Oleh itu, fabrikasi dipermudahkan melalui mekanisme setiap kali penyusunan. Selain itu, satu takuk bentuk persegi diwujudkan di dalam patch DRA dan berputar 45 darjah untuk mewujudkan nisbah paksi yang rendah. Sejak keseluruhan struktur bagi memastikan ia dipasang secara menegak di pinggir substrat, radiasi yang tinggi menyebabkan dalam pemadanan lebar jalur lebar. DRA antenna padat yang dicadangkan menunjukkan baik ciri-ciri radiasi dengan lebar jalur galangan 5.9GHz antara 3.9GHz dan Nisbah 9.8GHz dan paksi 1.25GHz antara nisbah 3.9GHz dan 5.15GHz dan paksi 900MHz antara 7GHz dan 7.9GHz.

CHAPTER 1

INTRODUCTION

1.1 Introduction

In the current world, recent technology demands growth in the spectrum of RF and Microwave fields to enhance the capability of mediums for a variety of applications in wireless communications, medical instruments and etc. In wireless Communications there is a great need in the development of antennas [1]. Thus, lots of attempts were derived towards designing of antennas for specific applications. Amongst them, micro strip patch antennas and Dielectric Resonator antennas are investigated for modern applications. Dielectric resonator antennas have been targeted in the past two decades as a potential solution for wideband antennas. Although they provide larger band and smaller size than patch antennas, they are usually designed for linearly polarized radiation, their performances in circular polarization is still limited [2], [3].

DRA's are Open resonating structures which are made from low loss microwave dielectric materials like ceramic, powder, liquid, and etc. They have a wide range of dielectric constant, ϵ_r (4-140). Efficient radiating modes are the low order modes because they have a low radiation Q -factor. Dielectric resonators have been used as high Q -factor elements in microwave-circuit applications since the development of low-loss ceramics in the late 1960s. A systematic study of dielectric resonators as radiating elements was first carried out in the 1980s by Long, McAllister, and Shen, who examined the characteristics of dielectric resonator antennas (DRAs) of hemispherical, cylindrical, and rectangular shapes. Dielectric resonators offer a more-compact alternative to waveguide-cavity resonators, and are more amenable to printed-circuit integration. For these applications, cylindrically shaped (puck) dielectrics resonators are typically used, fabricated from materials with relatively high dielectric constants for compactness. The dielectric resonators are also often enclosed in metal cavities to prevent radiation and to maintain a high Q factor, important for filter or

oscillator designs. By removing the shielding and with the proper feeding to excite the appropriate mode, it was found that these same dielectric resonators could actually become efficient radiators. In addition, by reducing the dielectric constant, this radiation could be maintained over a relatively wide range of frequencies. Usually, DRAs are mounted on a ground plane.

Efficient radiating modes are the low order modes because they have a low radiation Q -factor. Dielectric resonators have been used as high Q -factor elements in microwave-circuit applications since the development of low loss ceramics. They offer a more compact alternative to waveguide-cavity resonators, and are more amenable to printed circuit integration. For these applications, cylindrically shaped (puck) dielectrics resonators are typically used, fabricated from materials with relatively high dielectric constants for compactness [1]. The dielectric resonators are also often enclosed in metal cavities to prevent radiation and to maintain a high Q factor, important for filter or oscillator designs [4]. By removing the shielding and with the proper feeding to excite the appropriate mode, it was found that these same dielectric resonators could actually become efficient radiators. In addition, by reducing the dielectric constant, this radiation could be maintained over a relatively wide range of frequencies. Usually, DRAs are mounted on a ground plane. DRAs offer a high degree of flexibility and versatility over a wide frequency range, allowing for designers to suit many requirements.

Since the bandwidth of the dielectric resonator antenna is inversely related to its dielectric constant, wideband performance is best achieved by dielectric resonator antennas with low values of ϵ_r . By using simple analytical models to predict the radiation quality factor of cylindrical and rectangular dielectric resonators it was estimated that for $\epsilon_r = 10$, a rectangular shape could achieve a bandwidth of about 20%, and cylindrical dielectric resonator antennas could achieve a bandwidth between 30-40% for the lowest mode orders.

Why DRAs are the focus point of attentions. In order to answer this question, advantages of DRAs should be mentioned. As has been recently demonstrated, DRAs offer a high degree of flexibility and versatility over a wide frequency range, allowing for designers to suit many requirements. DRAs have the following advantages:

- DRAs have a low dissipation loss which enhances their radiation efficiency.
- One of the main aspects in the flexibility of DRAs, which is of a great

importance, is their resonant frequency. The designer can manipulate the size and shape of the structure to achieve its desired results in resonant frequency for a given application.

- Since the DRA size is proportional to $\frac{\lambda_0}{\sqrt{\epsilon_r}}$, where λ_0 is the wavelength at resonant frequency and ϵ_r is the dielectric constant of the dielectric resonator. Thus for the same frequency, there is a natural reduction in size, compared with micro strip antennas. Also, different values of ϵ_r , ranging from 4 to 100, can be used, thus allowing the designer the flexibility in controlling the size and bandwidth.
- Compared to other antennas structure, DRAs have a low radiation Q -factor. Since the relation between the bandwidth (BW) and quality factor (Q) of a DRA antenna is $BW \propto \frac{1}{Q}$, it means with a lower quality factor there is a wider bandwidth for dielectric antennas.
- One of the main concerns in array antennas is the high amount of coupling between two antennas due to small distance between them. The amount of coupling is proportional to the amount of surface waves of the structures. In DRAs there is no surface current and hence no surface wave exists. The result is the low mutual coupling between two resonators. This matter has ranked DRAs as the best candidate for array antennas.
- The different pattern shape for various applications is affordable via excitation of different modes within the DRA element. Also, the Q -factor of some of these modes will depend on the aspect ratio of the DRA, thus allowing one more degree of flexibility in the design.
- DRA antennas have a high dielectric strength, more than 200V/mil and high power capability. In addition, one of the main factors that is a demanding concern of technology, especially in space antennas, is the stability of materials against the wide temperature variation. DRA materials are stable in the range of -65 to 110 degrees.

1.2 Problem Statement

One of the basic problems associated with the design of a dielectric resonator antenna is that most of the proposed structures are linearly polarized antennas that are sensitive to the transmitter and receiver orientation. Circular polarization is achieved through a narrow band of the antenna impedance bandwidth. Certain mode excitation is applicable by a special complex circuitry or probe position to provide quadrature

signals. Besides, there is an incongruity between size and impedance bandwidth.

1.3 Objective

The objective of this research is divided into two categories:

- To design and characterize a new wideband dielectric resonator antenna that is workable for wireless applications.
- To make the structure circular polarized in the resonant frequency to achieve a wide axial ratio. The new structure of DRA will be designed, characterized, simulated, fabricated, and measured.

The behavior and properties of wideband circular polarized DRA will be investigated by simulation and measurement. Finally, this new structure will be modeled based on analytical methods to more understanding of behavior of the antenna.

1.4 Scope of Project

The main scope of this research is:

- To study and understand the techniques of designing wideband dielectric Antennas.
- To study and understand the circular polarized dielectric designs.
- To design a new wideband circular polarized dielectric resonator antenna.
- Enhance and optimize the performance using simulation and experimental techniques.
- Finalize the design, compile reports and write a conference or journal paper.

1.5 Thesis Organization

This thesis consists of five chapters, which is organized based on the following categories: Chapter 1 addresses a general definition and overview of the project, introduction, problem statement, objective and scope of the project.

In chapter 2, dielectric resonator antennas are reviewed and their advantages and disadvantages are discussed. Different types of polarization, feeding mechanisms for linear and circular polarization are introduced.

Chapter 3 addresses the antenna design methodology and design procedure. It presents different DR antenna configurations designed as well as their specifications.

Chapter 4 presents design verification and simulated and measured results for different features of the antenna such as reflection coefficient, axial ratio, gain and radiation patterns. Furthermore, a detailed analysis of parametric study is conducted. Finally, a comparison is made between measured results and simulation results using CST Microwave Studio Software.

Chapter 5 finishes the book with the theoretical and experimental works as well as several comments for future studies.

1.6 Summary

This chapter discussed the project introduction followed by problem statement, objective of the project, as well as scope of work. Finally, a short description of each chapter is briefly presented.
