

IMPLEMENTING MULTI HOP TRANSMISSION IN WIRELESS LOW RATE
IEEE 802.11 NETWORK

IDA SYAFIZA BINTI MD ISA

A project report submitted in fulfilment of the
Requirement for the award of the degree of
Master of Engineering (Electrical – Electronics and Telecommunication)

Faculty of Electrical Engineering
Universiti Teknologi Malaysia

JANUARY 2012

*Dedication to my beloved Husband and Daughter,
who has fulfilled my Heart with Love and Brightness*

ACKNOWLEDGEMENT

In the name of ALLAH, Lord of the Universe, and Peace and Prayers be upon His Final Prophet and Messenger. With the help from the numerous individuals, this thesis has successfully been done.

First and foremost, I would like to take this opportunity to express my appreciation and gratitude to my supervisor, Dr. Sharifah Hafizah Bt Syed Ariffin for her guidance, suggestion and full support to complete this project.

I would also like to express my sincere appreciation to my husband, Nur latif Azyze bin Mohd Shaari Azyze for his moral support, encouragement and providing his valuable time and effort during my research so that the project would succeed. Also to my daughter, thank you for your love and not giving Mama a hard time.

Special thanks go to my beloved mother, father, brother and sister for their support in all the stages of my study.

Finally, I am also thankful to my colleagues in Telekom lab and to all my friends in UTM for their assistance and understanding.

Thank you all

Ida Syafiza Binti Md Isa

ABSTRACT

An Ad Hoc networks are becoming more important in the daily lives. It can be used to instantly connect to local or remote networks such as the internet without the need of pre-existing infrastructure or centralized administration. The users of the network together will establish the infrastructure. The disadvantage of wireless communication is that it has limited range of radio transmission. Due to this, multiple network 'hops' may be needed for one node to exchange data with another across the network. In an ad hoc network, the nodes may not only operate as a host but also as a router to forwarding the packets to others nodes. There are variety of routing protocol targeted at this environment have been developed and most of them suffers from high overhead data traffic. The main purpose of this project is to develop a new routing strategy. The new routing is developed by using the existing network protocol that had been already used in network environments which is the Address Resolution Protocol (ARP). This new routing is used to maintain and establish routes in a vehicular ad hoc routing network. Many of the existing strategies nowadays are wasting these resources. By extending the ARP protocol with two new operation types, ARP Forward Request and ARP Forward Reply to allow the intermediate nodes to forward the request and reply, we have successfully manage to create a multi hop transmission in ad hoc network. The data can be sent through multi hop transmission until it reaches the destination. Measurement taken from a 3 nodes of 802.11b test bed demonstrate the new routing protocol for multi hop transmission can be used in an ad hoc network and it can perform well.

ABSTRAK

Rangkaian tanpa struktur tetap semakin menjadi kepentingan dalam kehidupan seharian manusia. Rangkaian tanpa struktur tetap ini boleh digunakan dalam menyediakan perhubungan diantara rangkaian tempatan atau rangkaian kawalan seperti laman sesawang tanpa memerlukan satu struktur rangkaian tetap. Pengguna didalam rangkaian perhubungan tersebut akan bergabung dengan sendirinya untuk membentuk satu rangkaian perhubungan yang tetap. Perhubungan tanpa wayar mempunyai keburukkan iaitu ia mempunyai kawasan rangkaian perhubungan yang terhad. Oleh itu, beberapa rangkaian untuk menghantar data dari satu nod to nod yang lain dalam rangkaian perhubungan yang sama di perlukan. Dalam rangkaian perhubungan tanpa struktur rangkaian tetap ini, setiap nod bukan hanya beroperasi sebagai penghantar tetapi juga nod yang digunakan sebagai pengantara untuk menjadi laluan penghantaran data dari mana-mana nod ke nod yang lain. Tujuan utama projek ini adalah untuk mencipta satu strategi penghantaran yang baru. Strategi penghantaran yang dicipta ini adalah dengan menggunakan strategi penghantaran yang sedia ada dan digunakan dalam sistem perhubungan iaitu protocol ARP. Strategi yang dicipta ini adalah untuk menjaga selain membina satu jalan penghantaran di dalam aplikasi penghantaran tanpa struktur tetap di antara kenderaan. Kebanyakan strategi penghantaran yang sedia ada kini tidak menggunakan strategi protocol ARP yang sedia ada ini. Dengan menambah baik protocol ARP ini iaitu dengan membawa ke hadapan pertanyaan dan membawa ke hadapan balasan untuk membenarkan pengantara nod menghantar pertanyaan dan membalas, pemprosesan data strategi ini berjaya dikurangkan. Selain itu data juga berjaya di hantar menerusi beberapa nod sehingga samapi ke destinasi. 3 nod yang menggunakan 802.11b diaplikasikan dalam eksperimen dan keputusan menunjukkan bahawa strategi baru yang dicipta untuk penghantaran data menerusi beberapa nod ini berjaya diaplikasikan dalam rangkaian perhubungan tanpa struktur tetap

CHAPTER 1

INTRODUCTION

1.1 Background

Nowadays, the technology for wireless communications has made tremendous advantages where it allows a very high mobility, efficient working and almost extreme economical. Moreover the Wireless Sensor Network (WSN) has become more crucial for mankind. The WSN is built of nodes from a few node to several hundreds or even thousands nodes, where each node is connected to a sensor. Each of the sensor network nodes consists of a radio transceiver with an internal antenna, a microcontroller, an electronic circuit for interfacing and an energy source. Devices such as cellular phone have now become necessity to everyone which allows people to communicate with each other with the urban coverage nearly everywhere around the world. Bluetooth and Wireless Local Area Network (WLAN) technologies have now become available and it facilitates easier living and creating the wireless environment.

Ad hoc is one of the communication technologies which provide the possibility for wireless devices to communicate directly with each other. Ad hoc mode allows all wireless devices to operate within the range of each other to discover and communicate in peer-to-peer fashion without using central access points. Ad hoc network is a network that makes pre-existing infrastructure obsolete and it provides

dynamic topology. Ad hoc network has the ability of self healing structure that makes the communication less vulnerable for failing links. This means that, even the communicating devices may be removed or added in the network, the information still can make its way through the networks to its final destination.

Due to the limited transmission range of the wireless network interfaces, sometimes the exchange data from one node to another may not be successful across the network. So, multiple networks “hops” may be needed to exchange data between the nodes across the network. In such a network, each of the nodes will not only operate as a host but also as a router where the forwarding packets from one node to another in the network may not be within direct wireless transmission range of each other. Each node that participates in an ad hoc routing protocol will allow it to discover ‘multi-hop’ path through the network to any other node. The ad hoc networking is also called infrastructure less networking, since the node in the network will dynamically establish routing among themselves to form their own network.

The existence of ad hoc technology and the ‘multi-hop’ network are useful for the Vehicular Ad Hoc Network (VANET) application. The VANET technology used vehicle as mobile nodes in the network to create a network. Every participating car in the network is turned by VANET into a wireless router or node. This allows car approximately 100 to 300 metres of each other to communicate and this creates a network with wide range. The cars may fall out of the signal and drop out of the network and other cars may join in, connecting vehicles to one another.

For the safety purpose, the system that integrated with this technology is beneficial to the police and fire vehicles where the communication of Vehicle to vehicle (V2V) application can be done even the nodes or vehicles can move around with no boundaries on their direction.

1.2 Motivation

Nowadays the IEEE 802.11 standard dominates the market and the implementing hardware is well developed. Ad Hoc protocol can be used for robustness and it can be deployed anywhere. This is useful for Vehicular Ad Hoc Network (VANET) which has grown out of the need to support the growing number of wireless products that can be used in vehicles. Moreover, as the mobile wireless devices and networks become increasingly important, the demand for Vehicle-to-Vehicle (V2V), Vehicle to Roadside (VRC) and Vehicle-to-infrastructure (V2I) communication will continue to grow where the nodes can move around with no boundaries on their direction. To support the communication in VANET network, a multi-hop concept is needed. Hence a new strategy for multi-hop transmission in wireless low rate ad hoc network with less overhead network traffic compared to existing protocols is developed.

1.3 Objective

The objectives of the project are:

1. To configure the low rate IEEE 802.11b platforms using Microchip WiFi Development Board.
2. To develop a multi hop routing protocol in C language.
3. To implement multi hop routing protocol on wireless Ad Hoc network.

Performances of the routing protocol will be evaluated base on the packet receives, packet loss, average time required for successful transmission and the throughput.

1.4 Scope of Work

The scope of this project includes developing software for the low rate 802.11b platforms in C language. The routing protocol of multi hop transmission using the existing network protocol, Address Resolution Protocol (ARP) on wireless Ad Hoc network is developed to send packets to the destination. This software will be embedded in the low rate 802.11b radio. The node will acts as a transmitter, receiver and a router.

The proposed routing protocol used the existing network protocol which is the Address Resolution Protocol (ARP). The ARP protocol utilizes to define the route or the path to the destination nodes. The query packet which is the ARP request will be broadcast to all nodes in the network in order to find the location of the destination. The forwarding nodes are implemented to find the routes to the destination. This new protocol comprises of two phases which are route discovery and data forwarding. In route discovery, if the nodes are in the same network, the ARP request or the query will be broadcasted. Nodes that hear the request will decide to broadcast the packet by replacing the source IP with its own IP. Therefore, at the destination node that receive this packet will then send a reply to the intermediate node and it will be forwarded via the route that have been established.

The development of this new routing began with the development of the state diagrams of the algorithm that illustrates the essential sequence of events. This eases the real test bed implementation. This project did not involve with the simulation but are developed in a real working implementation of a test bed that runs the routing protocol. The performance metrics such as packet receive, packet loss, the round trip time and also the throughput are analyzed. The test bed developed consists of three 802.11b and a laptop that can run a Wireshark.

1.5 Significant of the Project

This project is to develop a new routing protocol that can work in an ad hoc network. The development of the new routing protocol is based on the literature review on the existing routing protocol in the current communication network. The performance of this new routing protocol is verified with the implementation on a test bed in a two different environment. Depends on these outcomes, the feasibility of using this new protocol can be determined.

1.6 Organization of the Project

This report consists of five chapters. Chapter 1 contains the introduction to the project, the motivation, objectives, scope of work and the significant study of the project. Chapter 2 contains the literature review of the ad hoc network, the existing routing protocol and the concept of the Address resolution Protocol (ARP). In chapter 3, the methodology of the project is illustrated. This chapter details the hardware and software tools used. Besides, the testing method is also discussed here. In addition, the flow chart of the methodology and the flow chart of the programming are also explained here. Chapter 4 explains the result and the analysis of the experiments. The result of the different location of the experiment is also illustrated. Finally, chapter 5 concludes the report and suggests the future works.
