ABSTRACT

Study of lightning location is increased nowadays because of the high effect and hazard from lightning. Several techniques were developed to detect the lightning location. This project concentrates on the detection of a lightning location using the interferometry method. The system consists of four parallel plate antennas. Three of the antennas were placed at 14.5 meter apart to form two perpendicular base lines and the fourth is diagonally located at 75.58 meter distance away from antenna 2. The azimuth and elevation angle of the radiation source are determined by a set of three antennas, the fourth antenna is used to determine the exact position of the radiation source. The lightning signal was detected and recorded using Lecroy oscilloscope and the data obtained by all antennas were analyzed using the Matlab software. The system was controlled remotely using TeamViewer software to make work easy and more reliable. This project has detected only one lightning signal that can be analyzed. This situation happened because of the low probability of having a coincidence of lightning strike at location of the antennas. The result of the analysis is the azimuth and elevation angle and X-Y-Z location of the lightning signal detected. In general, the objective of present study was successfully achieved.

ABSTRAK

Pengajian berkenaan dengan lokasi kilat semakin meningkat pada masa kini disebabkan kesan kilat serta bahaya yang terhasil dari kilat. Beberapa teknik untuk mengesan lokasi kilat telah dicipta. Projek ini akan menekankan berkenaan pengesanan lokasi kilat menggunakan interferometri teknik. Sistem ini menggunakan empat plat antena yang selari. Tiga antena telah diletakkan 14.5 m antara satu sama lain untuk membentuk dua garisan bersudut tepat dan antena ke-empat telah dipasang 75.58 m dari antena 2. Sudut azimuth dan ketinggian dari sumber radiasi diperolehi dari tiga antena yang berdekatan dan antena ke-empat berfungsi untuk menentukan lokasi X-Y-Z kilat. Signal dari kilat dikesan dan direkod menggunakan osiloskopi Lecroy dan data yang diperolehi di analisis menggunakan perisian Matlab. Sistem pengesanan lokasi kilat ini menggunakan sistem kawalan jarak jauh menggunakan perisian TeamViewer untuk memudahkan kerja serta meningkatkan kebolehpercayaan sistem. Projek ini hanya dapat mengesan satu sumber dari kilat yang boleh dianalisis. Keadaan ini mungkin disebabkan lokasi antena yang dipasang dan kebarangkalian bilangan sambaran kilat dikawasan berkenaan. Keputusan dari analisis ialah sudut azimuth, sudut ketinggian dan koordinat X-Y-Z kilat. Umumnya, objektif projek ini telah dicapai.

CHAPTER 1

INTRODUCTION

1.1 Background

Since the world began, at almost every minute, lightning occurs over the face of the earth. Lightning is one of the amazing and beautiful phenomena in the world. Lightning produces its own style of light which can occur from the cloud to cloud, or from cloud to earth. Lightning produces very high current that is powerful enough to dig deep holes on earth, easily cut trees, move a car hundreds of feet, set fire to homes, kills human being, and so forth. Besides that, in the power system, lightning is a single largest cause of fault. It creates transient, and outages which disrupt electric power service and it is also a major effect of electromagnetic interference for electronic system.

Malaysia is located at $1^{\circ}7^{\circ}$ N in latitude and 100° - 119° in longitude which is in area of high level lightning activities. Therefore, the information on thunderstorm occurrence and local lightning flash characteristics are required. The information allow utility to minimize outage time, improve services reliability, decrease public safety hazards and so forth. Besides that, the information can be used to determine the lightning protection level at that location which can provides reduction in cost for lightning protection.

There are various techniques used nowadays to locate lightning and to determine various parameters produced from lightning. Each technique provide its own claimed performances.

1.2 Objective of Project

The objectives of this project is to understand the interferometry technique related to lightning location, to enhance the existing lightning locating system and to determine the lighting location from the system.

1.3 Scope of Project

In order to achieve the objective of the project, there is one scope that has been outlined. The scopes of this project is focused on the interferometry lightning locating system using four antennas.

1.4 Report Outline

This report consists of five chapters. The first chapter discusses the objectives and scope of this project as well as the summary of works. While Chapter 2 discusses more on theories and literature reviews that have been studied related to the project. It discussed interferometry system for lightning location. In Chapter 3, the discussion will be on the methodology of this project. In Chapter 4, the results and discussion of the project are discussed. The last chapter focuses on the conclusion and recommendations for further studies.

1.6 Summary of Works

The project began with a study on the interferometry system and the requirements for lightning locating system. Then follow the performance checking and troubleshooting of the previously developed system was carried out. After the troubleshooting and improvement of the system, the experiment to detect the lightning location was conducted. The results from the experiments were used in the analysis using Matlab programming.
