

**PHYSICAL ANALYSIS OF BLOOD SPATTER PATTERN ON CONCRETE
WALL**

TAN HUI KHIM

**A dissertation submitted in partial fulfillment of the requirements for the award
of the degree of Master of Science (Forensic Science)**

**Faculty of Science
Universiti Teknologi Malaysia**

JANUARY 2013

*A special dedication to my beloved mother and father, my supervisor Mr. Hashim Baharin, and my Co-supervisor Superintendent Soo Me Tong.
Thank you for your unconditional support.*

ACKNOWLEDGEMENT

First of all, I wish to express my sincere appreciation to my supervisors, Mr. Hashim Baharin, Superintendent Soo Me Tong for the valuable guidance, meaningful advices and moral support throughout my candidature to complete this dissertation project. This dissertation would not have been possible without their time and patience devoted to this dissertation. I have gained a lot of knowledge and experience from them during the process of completing this project.

Especially thanks to Asst. Prof. Dr. Umi Kalthom Binti Ahmad and ASP Zuraimi Bin Zam Zam for their guidance and help in completion some part of this dissertation that made this thesis possible.

Furthermore, I am truly grateful to my fellow Forensic Master students, research assistant, and laboratory assistant for their encouragement, moral support, and knowledge throughout the research.

Finally, I would like to take this opportunity to thank my beloved family for their continuous support, advices and motivation for me to complete this project.

ABSTRACT

Bloodstain pattern analysis is the study and investigation of the physical characteristics of blood spatter in order to reconstruct a crime scene event especially homicide crime scene. This study aims to analyze blood stain patterns on non-porous wall by using real blood which mainly focused in the comparison of impact spatter between several parameters. The parameters involved were in term of amount of blood, velocity, position of victim, distance, porosity of surfaces and directionality. In this study is undertaken to analyze cast-off stain (linear spatter), impact spatter (non-linear spatter) and drip (non-linear spatter) which caused by both sharp weapon and blunt weapon. The bloodstain pattern was produced by hit the blood-soaked sponge with weapon and swung back and forth in overhead. Results showed that as amount of blood increased as the number of drops and total coverage area increased. Total coverage area also affected by the various distances to wall; greater separation was found when the distance was further. In comparison of velocity, higher velocity was tended to generate finer droplets and vice versa. Bloodstain on porous surface and non-porous surface had significant difference as more blood drips were found on non-porous wall surface. For the area of convergence determination, result showed that impact angle was proportional to width to length ratio of blood drops. As impact angle decreased, the stain was found more elongated in shape. Minimum number of blow on and sequence of blow on cast-off stain was determined through the blood trails. Based on this study, impact spatter in term of velocity, directionality, position of victim, distance, blood volume, and porosity of surfaces can be differentiated. Area of convergence and impact angle can also be determined by using stringing method and mathematical method respectively.

ABSTRAK

Analisa corak kesan darah adalah kajian dan penyasatan ciri-ciri fizikal percikan darah dalam usaha untuk membina semula urutan tempat kejadian jenayah terutama pembunuhan jenayah. Kajian ini bertujuan untuk menganalisis corak kesan darah pada dinding bukan berliang dengan menggunakan darah tulen yang terutamanya tertumpu dalam perbandingan kesan percikan antara beberapa parameter. Parameter yang terlibat adalah kuantiti darah, halaju, kedudukan mangsa, jarak, keliangan permukaan dan arah. Corak kesan darah telah dihasilkan dengan memukul span yang direndam darah oleh senjata dan mengayunkan ke belakang dan ke hadapan. Keputusan menunjukkan bahawa semasa kuantiti darah meningkat, bilangan titisan dan jumlah kawasan liputan juga meningkat. Jumlah kawasan liputan juga dipengaruhi oleh pelbagai jarak ke dinding; pemisahan titisan darah yang lebih besar telah ditemui apabila jarak semakin jauh dari dinding. Dalam perbandingan halaju, halaju yang lebih tinggi cenderung untuk menghasilkan titisan halus dan sebaliknya. Kesan darah pada permukaan berliang dan permukaan tidak berliang mempunyai perbezaan yang ketara. Dimana bahawa darah jenis menitis lebih banyak ditemui pada permukaan dinding tidak berliang. Bagi penentuan kawasan penumpuan, keputusan menunjukkan bahawa sudut hentaman adalah berkadar kepada nisbah lebar dan panjang titisan darah. Sudut hentaman yang lebih mencondong menghasilkan titisan darah yang memanjang dalam bentuk. Bilangan minimum tamparan dan urutan tamparan juga telah ditentukan melalui corak kesan darah. Berdasarkan kajian ini, kesan percikan dalam jangka halaju, arah, kedudukan mangsa, jarak, kuantiti darah, dan keliangan permukaan boleh dibezakan. Kawasan penumpuan dan sudut hentaman masing-masing boleh ditentukan dengan menggunakan kaedah benang dan kaedah matematik.

CHAPTER 1

INTRODUCTION

1.1 Preamble

Blood spatters determinations are the inspection of the physical dimension, positions, and spreading or spurting model of blood spatter, for the sake of furnishing the evaluation of the external occurrences which could lead to original source. Bloodstains pattern analysis is an amazing investigation apparatus can be applied in reconstructing crime scene events. If a forensic scientist apprehends blood reacts in what manner during it exposing from a human body, and response in what manner during it touching a plane, subsequently an assumption is able to make to apprehend what was occurred and to decide if an offense taken place. An expert forensic investigator always would observe on the blood distributions produced by cast blood and try to reconstruct what was occurred.

Analyzing of blood spatters comprises external measuring of blood drops, spatter identification employing verified images or tests, the utilization of trigonometric method, and information of the movement's physic. By making good use of others form of crime scene evidences such as palm prints, instruments' mark, tyre prints impressions, biological evidences, chemical examination, and others. A forensic investigation team would gather all related evidences to re-generate a reasonable flow of a crime, and this is defended by others form of crime evidences.

The general practice of bloodstains spatter model examination reflects the elements of position, form, physical dimension, spreading patterns and others more

external behaviour of the blood spatters in a crime scene. However, blood patterns are a cluster of single bloodstain produced with the similar strike and the strength used. Greater parts of the bloodstains spatters of a model would suit in a reasonable physical dimension extent on a provided spatters classification. In the easiest structure, the spatter can be generated by a individual striking of consistent speed. For this example, a single blood spatter would emit far from the location of striking in a fan-like structure or dispersion of radiate. A whole blood distribution models are affected by several elements consisting, however unrestraint to the speed of certain striking strength, the direction of the administered power, an exterior patterns of an injury giving a blood origin, exterior structure, and blockage existed at the physical surrounding.

1.2 Problem Statement

Bloodstains are existed at majority of the crime areas implicating anger would consequently provide the forensic investigators with extra knowledge to identify the crime's flows, from which might be taken involved betwixt the suspect and also the victim. Currently, bloodstains spatter in crime scene as well as bloodstains from either suspect or victim's clothes can be very helpful in order to use in assuring or discredit an uncertain conclusion relating with crime events and the flows. However, bloodstains spatter patterns are difficult to link with the possible weapon used as to whether blunt weapon or sharp weapon are used.

Furthermore, there is little research done on bloodstain patterns analysis on painted concrete wall. This is due to the large painted wall is not easy to be accessed in a normal research laboratory. Therefore, for the sake to make sure the restoration of bloodstain proof or clue we need to understand the physical properties of bloodstain pattern and proper documenting must be done.

1.3 Research Objectives

Objectives for this research are:

- i. To compare the impact spatter of bloodstains in terms of directionality, velocity, impact angle, position of blood source, distances, blood volume, and porosity of surfaces.
- ii. To determine the point of convergence, impact angle, minimum number of blow, and sequence of blow of bloodstains on wall.

1.4 Hypothesis Statement

The area of convergence can be determined from bloodstains by using string method and mathematical calculation. The directionality, velocity, impact angle, position of victim, distances, blood volume, and porosity of surfaces can be differentiated from the various bloodstain patterns on wall. Analysis of bloodstains pattern can reveal information regarding minimum number of blow, and sequence of blow on wall.

1.5 Significance of Study

Blood spatter can always be found easily in most of the crime scene especially for both sexual assault and homicide cases. Therefore, this study is essential for investigator in reconstructing the whole crime event in which the bloodstain spatter pattern analysis can act an important role. Generally, this study could be used to assist them in determining the point of convergence, position of blood source, and possible type of weapon used.

1.6 Scope of Study

In this research, the surface matrices used is mainly focus on brick wall. Two major categories of weapons used are blunt objects and sharp objects respectively. Further studies were made by conducting a series of bloodstains pattern analysis which encompasses the impact angle, position of victim, area of convergence and the sequence interpretation of bloodstains pattern.
