Abstract: The objective of this paper is to compare the results of a solid rocket motor’s performance between theoretical calculations with empirical data collected from a static thrust bench in Propellant Laboratory, School of Aerospace Engineering, University Science of Malaysia. In this experiment, a simple and cheap solid propellant is manufactured, which consists of chemical compounds of potassium nitrate (KNO3), sulfur (S) and sugar (C12H22O11). Lesson learnt from this experiment will allow further research on the rocket’s flight trajectory prediction model being formulated for the completion of the dissertation.

Keywords: Internal Ballistic, Solid Rocket Motor, Solid Propellant, Static Thrust test, Thrust and Pressure Profile

Nomenclature

\[ m_p = \text{Propellant mass} \]
\[ I = \text{Impulse} \]
\[ I_{sp} = \text{Specific Impulse} \]
\[ g = \text{Gravitational acceleration} \]
\[ V_p = \text{Propellant Volume} \]
\[ \rho_p = \text{Propellant Density} \]
\[ R = \text{Radius} \]
\[ D = \text{Diameter} \]
\[ L_c = \text{Motor Case length} \]
\[ W = \text{Grain web thickness} \]
\[ t_b = \text{Burn time} \]
\[ r = \text{Regression rate} \]
\[ F = \text{Thrust} \]
\[ m = \text{Mass flow rate} \]
\[ A_t = \text{Throat Area} \]
\[ X = \text{Throat design permutation coefficient (0.95-1.10)} \]
\[ c_* = \text{Characteristic Velocity} \]
\[ P_c = \text{Chamber Pressure} \]
\[ E = \text{Nozzle Area Expansion Ratio} \]
\[ A_b = \text{Burn area} \]
\[ A_{port} = \text{Port area} \]
\[ N = \text{Number of grain segments} \]
\[ I_o = \text{Isp efficiency} \]

Subscripts:
o=Initial
i=Value at time increment i
port=Grain port variable
p=Propellant
e=Exit
c=Motor case
avg=Average

1. Introduction

This paper presents a work in progress to study the flight performance of a ballistic rocket for optimization of range. Detail study on solid rocket propellant motor design had done by theoretical and experimental method. In this experiment, a simple and cheap solid propellant is manufactured, which consists of chemical compounds of potassium nitrate (KNO3), sulfur (S) and sugar (C12H22O11).

The expected output of this research project “Preliminary design of short range ballistic rocket with prescribed trajectory”, a rocket ballistic model which has a gross lift-off weight 20 N. So the motor for this ballistic rocket had to produce thrust between 20 and 80 N, and total impulse of less than 200 Nsec. This
solid rocket was to carry the ballistic rocket and payload to an altitude at range 100 to 200 m. To meet this requirement, the solid propellant rocket motor to be developed. The process included designing, analysis and construction of the motor. In designing the motor, a propellant formulation was used from various source and initially verified to find the best compounds. This formulation was then used to determine the interior ballistic properties and grain geometry that allow the motor complete the mission. Then, all component of the motor including case, nozzle and the actual propellant segments had to fabricate.

After the formulation of the propellants was complete, small batches of propellant were made and test fired to ensure the propellant properly mixed and cast. After that, full size motor segments were cast to verify the nozzle design. A complete motor was fabricated to be used in static test firings. An empirical data from this static test is collected to be analyzed and compared to the theoretical calculation.

2. Solid Rocket Motor Modeling

This section focused on determining the propellant characteristic, sizing the solid rocket motor and also modeling the pressure and thrust profiles. The mathematical models that had been derived from the propellant configuration will be compared to the test data.

2.1 Internal Ballistic

2.1.1 Propellant characteristic

In this project, a simple and cheap propellant was cast: potassium nitrate (KNO₃), sulfur (S) and sugar (C₁₂H₂₂O₁₁). The mixture of the compound 75% KNO₃, 10% S and 15% (C₁₂H₂₂O₁₁) is selected based on initial experimental result. The compound properties shown in the table 2.1 collected from PEP code.

<td>6.30:1</td>
</tr>
<tr>
<td>Characteristic velocity</td>
<td>863.43 m/s</td>
</tr>
</tbody>
</table>

Table 2.1 Properties of 75% KNO₃, 10% S and 15% (C₁₂H₂₂O₁₁). (Extracted from PEP code)

The first step is to determine the propellant mass, volume and port geometry:

\[ m_p = \frac{I}{I_{sp} g} \]  \hspace{1cm} (2.1)

\[ V_p = \frac{m_p}{\rho_p} \]  \hspace{1cm} (2.2)

For cylindrical grain geometry:

\[ R_{port} = \sqrt{R_c^2 - \frac{V_p}{L \pi}} \]  \hspace{1cm} (2.3)

The web distance:

\[ W = R_c - R_{port} \]  \hspace{1cm} (2.4)

The burn rates:

\[ t_b = \frac{W}{r} \]  \hspace{1cm} (2.5)

And the average thrust:

\[ F_{avg} = \frac{I}{t_b} \]  \hspace{1cm} (2.6)

The second step is to determine the throat area and exit area of the nozzle:

\[ m_{avg} = \frac{m_p}{t_b} \]  \hspace{1cm} (2.7)

\[ A_t = X \left( \frac{m_{avg} c^*}{P_c} \right) \]  \hspace{1cm} (2.8)

\[ A_e = \varepsilon A_t \]  \hspace{1cm} (2.9)

The next step is to model the mass, thrust and pressure in this design. Therefore to estimate the initial number of segments for given area:

\[ A_{bo} = \frac{m_{avg}}{\rho_p r} \]  \hspace{1cm} (2.10)

To analyze the thrust, pressure and mass profile, the burn duration is taken as a reference \( \Delta t \). At time \( t_i \), web distance burned is:

\[ \Delta W_i = r t_i + \Delta W_{i-1} \]  \hspace{1cm} (2.11)

And the burn Area is:

\[ A_{bo} = 2\pi N \left( R_{port} + \Delta W_i \right) \left( \frac{R_c + 2 \Delta W}{N} \right)^2 \]  \hspace{1cm} (2.12)

The mass flow rate at any instance \( t_i \) is:

\[ m_i = \rho_p r i A_{bo} \]  \hspace{1cm} (2.13)

Chamber pressure at \( t_i \):

\[ P_{ci} = \frac{m_i c^*}{A_i} \]  \hspace{1cm} (2.14)
Thrust
\[
F_i = m_i I_{sp} g + \left( P_e - P_{atm} \right) A_e
\]  
(2.15)

Where \( P_e \) at \( t_i \) determined from:
\[
P_{e_i} = P_{e_i} \left( 1 + \frac{y-1}{2} \frac{M_e^2}{\gamma} \right)^{\frac{\gamma}{\gamma-1}}
\]  
(2.16)

And motor mass;
\[
m_{i+1} = m_i - m_i \Delta t
\]  
(2.19)

3. Static Thrust Testing

This section addresses the static thrust testing includes planning, fabrication and development of the solid rocket motor based on previous section. The final test data recorded from static thrust bench apparatus to be analyzed.

3.1 Test plan

Several stages of development were accomplished before the actual motor was fabricated. The first is to gain experience in handling and mixing the materials used in this solid propellant. Once the tasks were completed, small segment of the solid propellant is tested to validate the mixture of the propellant. After that, static firing of the motor was performed to verify the predicted performance.

3.2 Propellant Segment and Solid Rocket Motor Fabrication

As mentioned before, a simple and cheap propellant composition selected, that is of potassium nitrate (KNO₃), sulfur (S) and sugar (C₁₂H₂₂O₁₁). The castings of the propellant were in simple plate. It is necessary to gain experience in mixing and casting this propellant. The compounds had been tested ranging from 60% to 80% potassium nitrate (KNO₃) and from 10% to 40% sugar with or without sulfur. And the based on the result from each compounds, 75% KNO₃, 10% S and 15% (C₁₂H₂₂O₁₁) were selected. After the mixing and casting process was completed, the propellant segments were ready to be loaded into the motor.

Then the next step is to fabricate the rocket motor and the nozzle. The nozzle was made out and machined from aluminum alloy. A picture of the nozzle is shown in figure 3.1.

![Figure 3.1 Nozzle](image)

Once the motor was fabricated and assembled, it was ready to be installed to the static test bench. Figure 3.2 show a fully assembled motor.

![Figure 3.2 Fully assembled Solid Rocket Motor](image)
3.3 Instrumentation and data Acquisition

The static test bench apparatus used shown in figure 3.3. The motor was mounted on the test stand in a horizontal configuration as shown in figure 3.4.

![Figure 3.3 Static Thrust Test Bench](image)

![Figure 3.4 Rocket Motor on static test](image)

3.4 Test Data

The static test on the solid rocket motor was conducted at Propulsion Lab, School of Aerospace Engineering, University Science of Malaysia. Figure 3.5 shows the thrust profile measured during static test.

![Figure 3.5 Experimental Thrust Profile](image)

4. Performance Analysis: Theoretical and Empirical data

The thrust profile measured from static test will be compared and matched to the predicted profile. The other data, pressure profile, motor mass during burn and burn area derived and modified based on experimental thrust data before compared to the predicted data.

![Figure 4.1 Theoretical and Experimental Thrust Profile](image)

![Figure 4.2 Theoretical and Modified Chamber pressure](image)
The data collected were analyzed and matched to the thrust predicted in the model. It is clear the thrust profile was different from the one predicted. The two main assumptions that was invalid for test; i) Constant burn rate ii) Constant throat area

Without pressure data and the St. Robert coefficient and exponent for burn rate correlation, it was difficult to predict the precise burn rate during test. However by examining the experimental thrust profile a burn rate could be postulated to decrease approximately linearly during the course of the test.

The other important information that can be obtained from the thrust test is the specific impulse efficiency. The Isp efficiency of the motor can be derived from the thrust by;

\[ \eta_o = \frac{\int_0^t F dt}{I_{sp} \int_0^t m dt} \]  

(5.1)

From the figure 4.1, the experimental thrust profile is completely different from the theoretical thrust profile. The burn time duration for experimental, 5.56 sec is 15% faster than measured from calculation that is 6.5 sec. For experimental and modified graph, trend line had been added to ease the analyzing and comparison.

For modified chamber pressure profile, figure 4.2, shows the chamber pressure is higher than the predicted data. The differentiation is nearly 20% average along the curve.

For modified and calculated motor burn area and mass of propellant profile, figure 4.3 and figure 4.4 shows there are compromise between the theoretical and modified profile.

Table 4.1 shows the comparison summary of experimental and theoretical calculation of the thrust profile;

<table>

5. Conclusion.

The data collected were analyzed and matched to the thrust predicted in the model. It is clear the thrust profile was different from the one predicted. The two main assumptions that was invalid for test; i) Constant burn rate ii) Constant throat area

For modified chamber pressure profile, figure 4.2, shows the chamber pressure is higher than the predicted data. The differentiation is nearly 20% average along the curve.

For modified and calculated motor burn area and mass of propellant profile, figure 4.3 and figure 4.4 shows there are compromise between the theoretical and modified profile.

Table 4.1 shows the comparison summary of experimental and theoretical calculation of the thrust profile;
The Isp efficiency of the motor test is summarized in table 5.1.

Table 5.1 Isp Efficiency of static test

Even if there are differentiation between the theoretical calculation and empirical data, useful data have been collected to improve the next rocket motor design for flight testing to predict the ballistic rocket trajectory.
