ACKNOWLEDGEMENT

I would like to thank my family, especially my dad for providing wisdom, encouragement and support in good times and bad. No matter what, they have been to keep me focused and on the path to success. I would not be where I am today without their love. I must also thank my supervisor, Assoc. Prof. Dr. Abu Sahmah bin Mohd Supa'at for his patience, advice and expertise. His mentorship style, guiding rather than leading, has allowed me to strengthen my intellectual wings and tackle problems on my own. When I needed it, he was always ready with a helpful suggestion as well explanation. To all my friends thank a lot for all supporting.

ABSTRACT

The demand for data traffic has initiated the development of optical telecommunications. Due to explosive growth of optical network, has brought forward an increased need for guided-wave optical component. The purpose of this work is to investigate the temperature profile in the thermo-optic waveguide. Here, we use one and two dimensional model to analyze the thermal model. We focus on polymer waveguide since these technology is attractive for many advantages, including large thermo-optic coefficient (for Polyurethane (PUR): $dn/dt \sim -3.3^{-4} \text{ K}^{-1}$) and low thermal conductivity ($\sim 0.19 \text{ W m}^{-1} \text{ K}^{-1}$). The buried and rib waveguide structure is used for two dimensional model thermal analysis. We interested to see how heating the heater will change the refractive index and change the profile in the waveguide. Thermal coupling became next task of this project. We analyze the effect of heater to the nearby waveguide. To perform this analysis, we utilized a commercial finite element method (FEMLAB 2.0), which is a tool for PDE-based multiphysics modelling in an interactive environment-MATLAB. The simulated result will use one and two dimensional model respectively. Effective index change is dependency of heater size as well as distance between core to the heater. Increasing $1\mu\text{m}$ of heater width will reduce -0.1 of dn_{eff}/dt it also increasing the power consumption. Thermal coupling is related to waveguide spacing and depth. The coupling estimation is increase with the waveguide depth but decrease with the waveguide spacing. Apply trench structure can reduce the thermal coupling estimation, K. The temperature of heated waveguide decreases as the trench depth increases, therefore it requires less power in performing its function.

ABSTRAK

Perkembangan terhadap komunikasi optik bermula dengan permintaan terhadap pengangkutan data. Peningkatan yang cepat memberi peluang terhadap penggunaan komponen gelombang pandu. Matlamat di sini adalah untuk mencari kesan suhu terhadap gelombang yang di panaskan. Oleh itu, penggunaan satu dan dua dimensi digunakan didalam analisis kesan haba ini. Analisis ini dilakukan menggunakan bahan polimer kerana ia mempunyai pemalar haba optik yang tinggi ($dn/dt \sim -3.3^{-4} \text{ K}^{-1}$) dan juga pengaliran arus elektrik yang rendah ($\sim 0.19 \text{ W m}^{-1} \text{ K}^{-1}$). Model haba menggunakan dua bentuk struktur gelombang yang berbeza iaitu penanaman (buried) dan juga melengkung (rib). Kami ingin melihat bagaimana haba memberi impak terhadap perubahan indek bias dan juga terhadap profil gelombang. Selepas itu, fokus terhadap perangkai haba (thermal coupling) di lakukan. Analisis pemanas terhadap gelombang yang bersebelahan dilakukan. Untuk melakukan semua analisis ini kami menggunakan komersial perisian iaitu FEMLAB 2.0 yang mana menggunakan asas fenomena fizik model dan juga persamaan matematik. Ia juga interaktif dengan perisian MATLAB. Simulasi akan menggunakan satu dan dua dimensi. Perubahan indek bias bergantung kepada saiz pemanas dan juga jarak di antara teras (core) kepada pemanas. Peningkatan sebanyak $1\mu\text{m}$ kelebaran pemanas akan mengurangkan -0.1 perubahan indek bias (dn_{eff}/dt) dan ini akan meningkatkan penggunaan kuasa. Manakala, perangkai haba (thermal coupling) amat bergantung kepada jarak di antara dua gelombang dan juga kedalaman teras. Nilai ini, K akan meningkat bergantung kepada jarak kedalaman gelombang dan mengurangkan sekiranya jarak di antara dua gelombang meningkat. Penggunaan kaedah perparitan (trench) akan mengurangkan nilai perangkai haba, K . Suhu gelombang yang di panaskan akan berkurang sekiranya kedalam parit (trench depth) meningkat. Oleh itu, ia akan menjimatkan penggunaan kuasa di dalam melakukan sesuatu fungsi.

CHAPTER 1

INTRODUCTION

Guided wave optics will play an increasing and important role in optical communication networks and optical sensor systems. In particular, polymeric waveguide devices are being developed; because the process can be low-cost, and high manufacturing output can be achieved. The low temperature fabrication process of polymer waveguide also gives the designer a large degree of freedom. Because most polymer materials have a thermo-optic coefficient an order of magnitude larger than that of silica, thus, they can be temperature tuned over a wider spectral range (Edwin Y. B. Pun and W.H. Wong, 2002).

In general polymer has a temperature dependent refractive index which is known as the thermo optic (TO) effect. Recently, the active optical glass waveguide utilizing the TO effect such as modulators and switches has been demonstrated (M.Haruna and J.Koyama ,1982). In 1989, there is published paper due to application of TO which is using polymer waveguide to make a switch. The author demonstrated that effective index changes at least one order higher than those obtained with the electro optic effect in LiNbO_3 are found (M.B.J. Diemeer, J.J. Brons and E.S. Trommel, 1989). Two years ago, the researcher (H.P. Chan, C.K. Chow and Alok K. Das 4, 2003), found that by using the polymer material in application of digital optical switch (DOS), there can reduces the crosstalk value.

Nowadays, there have a lot of research to find a robust material or versatile in optic communication application. Figure 1 shows the material that used until 2001, polymer contribute only few percentage.

1.1 Statement of the Problem

The explosive growth of the Internet, and the emergence of a strong wireless market are driving these changes, and optoelectronic components are fundamental enablers of this transformation. This combination of optical and electrical technologies allows data to be generated, transported and manipulated at high rates. Today, optoelectronics are being integrated into existing networks. By 2007, all-optical networks will most likely be needed (John Stafford, 2001).

Today's components and packages are too costly as well as too cumbersome. The industry will need to move to new technologies, such as flip chip instead of wire bond, and multichip modules to reduce package size (John Stafford, 2001). Still need a lot a research in this field due to demanding of optical communication.

As the new technology trends to increase the speed and the bandwidth for communications in wide area networks, the all optical network becomes a good choice as a solution for that problem. New devices and materials using linear or non linear effects of light are extremely useful for such networks because of their compatible speed (Mario L and Jose A.M. Pereira, 1996). Our project use polymer material to build optical waveguide. Recently, development on optical polymer waveguide will used electro –optic to implement the device. Because polymer has large TO coefficient, we will apply this effect to implement future device.

1.2 Integrated Optics in Polymers

Polymer materials are of great interest in integrated optics as they can be tailored to meet specific applications. The thermo-optic effect is large in these materials $-1 \times 10^{-4} \text{ K}^{-1}$ to $-4 \times 10^{-4} \text{ K}^{-1}$ which leads to power efficient dynamic components. They are potentially low cost and rapidly processed by direct photo patterning or reactive ion etching. Waveguide can be designed with very large or very small index contrast between core and cladding (0% – 35%). Polymer can also have very low optical loss $<0.1 \text{ dB/cm}$ at the telecommunication wavelengths 1310 nm and 1550 nm (John M. Senior, 1992). Cross linked polymer systems operated above the glass transition temperature even allow for waveguides free of stress induced scattering and birefringence. Polymer material classes used in integrated optics include acrylates, polyimides, polycarbonates and olefins (Robert Blum, 2003).

Realized polymer devices cover a wide range of optical applications like switches, couplers, filters, attenuators, polarization controllers, dispersion compensators, modulator, laser and amplifiers (R.T. Chan,1993).Even 3D multi layer architectures of integrated circuits are possible as successive layers are deposited by simple spin coating (S.M. Garner et al, 1999).Table 2 compares several typical

materials used in integrated optics. In almost all categories polymers exhibit excellent values. However, it is difficult to combine all these properties in single material.

Table1.2: Typical properties of waveguides in popular materials used in integrated optics. The refractive indices of the core and cladding materials are denoted by n_{cor} and n_{clad} respectively.

	Propagation Loss [dB/cm]	Refractive Index	Index Contrast ($n_{\text{cor}}-n_{\text{clad}}/n_{\text{cor}}$)	Birefringence	T/O Coef.dn/dt [K ⁻¹]	Max. Modulation Freq.
Silica	0.1	1.5	0-1.5%	10 ⁻⁴ -10 ⁻²	10 ⁻⁵	1kHz (TO)
Silicon	0.1	3.5	70%	10 ⁻⁴ -10 ⁻²	1.8×10 ⁻⁴	1kHz (TO)
Polymers	0.1	1.3-1.7	0-35%	10 ⁻⁶ -10 ⁻²	-1×10 ⁻⁴ - - 4×10 ⁻⁴	1kHz (TO)
Lithium Niobate	0.5	2.2	0-0.5%	10 ⁻² -10 ⁻¹	10 ⁻⁵	40GHz (EO)
Indium Phospide	3	3.1	0-3%	10 ⁻³	0.8×10 ⁻⁴	40GHz (EO)
Gallium Arsenide	0.5	3.4	0-14%	10 ⁻³	2.5×10 ⁻⁴	20GHz (EO)

Most serious problems in connection with polymers are environmental stability (temperature, humidity) and commercial availability. Thermal aging due to oxidation is often observed in organic materials as well as water incursion and the associated optical absorption from the overtone bands of the OH stretch (Robert Blum, 2003). However, these problems have been solved by many manufacturers (e.g. AlliedSignal, JDS Uniphase, Du Pont, Dow Chemical) and some materials even passed the Bellcore 1209 and 1221 test (R, Moosburger et al, 1996).

Unlike silicon, silica or InP, polymers are materials are designed by chemists to meet specific needs. Their usage is often hindered by patents and they are seldom sold or manufactured in small quantities as needed for integrated optics (J.D. Plumber, M.D. Deal and P.B. Griffin, 2000). Therefore commercially available polymers are usually built for other applications like microelectronics, display or

furniture coating. By chance, some of them also show desirable optical characteristics like BCB (Cyclotene by Dow Chemical).

1.3 Scope of this Work

This project is about an investigation of temperature profile in the thermo-optic waveguide due to the effect of having thin film heater on top of polymer waveguide structure by using the one and two dimensional model. Here, we would like to determine the effective index change from the change of temperature. By heating the heater, it will distribute the heat in the surrounding area and cause increasing the temperature in the waveguide structure.

In the way to analyze the TO effect, we will design thermal model based on two different structure which is rib waveguide structure and buried waveguide structure. The lateral heat diffusion distance in both structures will be studied. Two phenomena will be studied seriously, which is the distance from heater to the core waveguide (H) affect the effective index change. We also interested to investigate how heater size would affect the key parameters in modelling waveguide structure.

Thermal coupling became an issue when we have two waveguides in parallel. The structure will consists of two square waveguide. Due to thermal phenomena, heat one of the waveguide will effects nearby waveguide. Actually, these are unwanted phenomena and will degrade the devices performance. The relationship between them is known as thermal coupling estimation. Here, we will determine these values and try to figure out the way to reduce these effects. One method is by applying the trench structure. All the simulation is done using software named FEMLAB. The result can be obtained by GUI (Graphical User Interface). This software apply finite element as a method to solve all the problems.

1.4 Overview of this Report

This section outlines the organization of the work contained in this thesis. Throughout this thesis we have seven chapters including the conclusion. A brief history of integrated optic is discussed in Chapter 2. Follow with the literature review of this project. Several papers are discussed under section 2.2 sub topics.

In Chapter 3, all the theory that applies for the project progress is explained briefly. The discussion start with phenomena that cause light can travel in the waveguide. Maxwell equation are introduces to get wave equation. Then, the types of the structure are discussed following with several type of control waveguide. But for this project, we focus on thermo-optic control. At the end of this chapter, the subtopic is on polymer waveguide.

Chapter 4 is about the methodology of the project. Since we used the numerical method in the way to get the result, a basic theory of finite element method is discuss. Thermal analysis, which is the heat transfer equation are explain due to the one and two dimension respectively. Thermal model including rib and buried waveguide structure is explained under section 4.3. Lastly, a quick step on simulation used FEMLAB software is shown.

The result section is divided into two sub topic which is thermal model and thermal coupling. Under thermal model we show the result for rib and buried structure. One dimensional is also shown under this sub topic. All the parameter that will be influence the performance of effective index change is shown in this topic. Discussion and analysis or data interpretation are shown in Chapter 6. A lot of issue is discussed here. Last chapter is about the conclusion of the project throughout this course.
