Exploring IT Professionals' IntentiontoUseSoftwareDevelopmentRisk AssessmentFramework

ELNAZ FARHANG DAREHSHORI, NORSHIDAH MOHAMED International Business School Universiti Teknologi Malaysia Level 11, HEAMC Building, JlnSemarak, 54100 KL MALAYSIA. elfar808@gmail.com.norshidah@ic.utm.my, http://www.ibs.utm.my

Abstract: - The paper builds on the Theory of Reason Action (TRA) and Technology Acceptance Model (TAM) to develop a research model in exploring information technology (IT) professionals' intention to usea risk assessment framework in the context of software development. A total of 150 survey questionnaires were distributed on a convenient basis to Malaysian IT professionalsin a software company; 106 were received. Out of this number, only 100 were used for analysis. There is evidence to suggest the application of TRA and TAM in explaining the intention to use a risk assessment framework in Malaysian software development environment. Other implications and future areas for research are discussed herein.

Key-Words: -risk assessment, software development, technology acceptance model, theory of reasoned action

1 Introduction

The rapid development of information technology (IT) sees new business models such as electronic commerce and mobile commerce. To stay ahead of competitors, typical business organizations invest in information and communication technologies (ICT) for operational efficiency.Companies whose primary focus is on software business invest in tools to enhance their internal software development effectiveness.

While many technological tools have emerged since the explosive growth of the Internet, it is evident that software projects have shown an increase in size, complexity and number[1]. Whilethe success of software projects is becoming more critical for these companies[2],a high percentage of software projects still fail to meet their objectives [3]. Hence, a major area of concern for software development companies revolves around the successful completion of their projects[4; 5].

To help software companies better manage the software project, researchers have devoted considerable attention to exploring risk factors.Prasanta et al. [6] defined risks as possible problems.

The notion of managing risks is to minimise the threat output of an organisation [7; 8]. In software project management, risk management is used to avert the impact of risk or decrease the impact of threats by resolving potential problems before occurring[9]. Ezamly and Hussin [10] proposed that risk method could be used in practice and could prevent software project failure.Since understanding related risks is important to ensure software project success, numerous studies were conducted to identify these risks and their categories [11; 12; 13].

There are notable risk assessment models in software projectliterature[14]:*Risk* Drivers Method, Software Engineering Risk Model(SERIM) and Software Risk Assessment Model (SRAM). In Malaysia, the Malaysian Administrative Modernisation and Management Planning Unit developed and commissioned the Risk Assessment (MyRAM) [15].MyRAM provides Guideline guidelines for both private and public organizations to conduct security risk assessment in information security management systems. It is based on ISO27001: 2005 and 27002:2005.

Organizations that wish to move beyond risk assessment and learn from prior experience may complement MyRAM with another framework commonly known as the Corrective and Preventing Action (CAPA). The combination of both sets outto overcome the limitations of each framework which was later coined as Risk Assessment and Corrective and Preventive Actions or CAPRA[16]. The scope of both covers an identification of a risk team, assets, threats and, safeguarding mechanisms and vulnerability assessment in each stage of software development.

The paper considers the integrated MyRAM and CAPA as an innovation in software projects that deals with risk assessment of such. The research aims to explore the acceptance of MyRAM and CAPA. Thus, the research questions areset out: (1) What is the acceptance of MyRAM and CAPA among IT professionals? (2) Do subjective normperceived awareness and perceived importance correlate to risk assessment framework acceptance?

2 Problem Formulation

This section examines the theoretical base for the research. The research builds on the Theory of Reasoned Action or TRA (Fig. 1) andTechnology Acceptance Model or TAM (Fig. 2).Based on TAM, we construct external variables as perceived awareness, perceived importance and subjective norm. Acceptance of the risk assessment framework in the present research refers to the perceived ease of compliance to it, perceived usefulness by users and intention to use it.

Fig. 1 Theory of Reasoned Action[14]

Fig. 2Technology Acceptance Model [10]

Accordingly, we hypothesize the following:-**H1:** Perceived usefulness is positively correlated to intention to use MyRAM and CAPA.

H2: Perceived ease of compliance is positively correlated to intention to use MyRAM and CAPA.

H3: Perceived ease of use is positively correlated to perceived usefulness of MyRAM and CAPA.

H4a:Subjective norm is positively correlated to perceived ease of compliancetoMyRAM and CAPA. **H4b:**Subjective norm is positively correlated to perceived usefulness of MyRAM and CAPA.

H4c:Subjective norm is positively correlated to intention to use MyRAM and CAPA.

H5a:Perceived importance is positively correlated to perceived ease of compliancetoMyRAM and CAPA.

H5b:Perceived importance is positively correlated to perceived usefulness of MyRAM and CAPA.

H5c:Perceived importance is positively correlated to intention to use MyRAM and CAPA.

H6a:Perceived awareness is positively correlated to perceived ease of compliancetoMyRAM and CAPA. **H6b:**Perceived awareness is positively correlated to perceived usefulness of MyRAM and CAPA.

H6c: Perceived awareness is positively correlated to intention to use of MyRAM and CAPA.

Fig. 3 shows the present research model.

Fig. 3Research Model

3 Problem Solution

This section discusses the research design and findings.

3.1 Research Context, Population and Sampling

A software company in Malaysia was selected as a case study for the research. ItsITprofessionalswere the research participants. A survey questionnaire was used as the instrument. MyRAM and CAPA as a new software risk assessment framework waschosen as an innovative tool in managing risks for software implementation.

The target population is set out to be IT professionals in the selected software company. The estimated population for the research is 202. The sample is 150 comprising IT professionals working as Chief Information Office (CIO), software programmers, network analysts, software designers, system administrators, risk assessment team including members project advisor, project manager, software engineers and IT officer. Permission was granted by the company for the researchers to collect the data and responsesto the survey are on voluntary basis. Thus, the research used a convenient sampling approach. For confidentiality reason, the company remains anonymous.

3.3 Constructs and Measures

Table 1shows the sources and definitions for the measures used in the research.

Table 1. Constructs, Sources and Definitions.

3.3 Data Analysis and Findings

Prior to collecting the data, a pilot test was conducted. A total of 30 IT employees of the company participated in the pilot test. SPSS version 16 was used to run the analysis. The pilot test results show that the Cronbach's alpha (α) for all measures is greater than 0.70 [24]; suggesting reliable measures for all constructs. Therefore, no measure was omitted for the final data collection purpose. A remaining total of 120 survey questionnaires were distributed. A total of 76 were received but only 100 were used in the final analysis. The data for the pilot study were combined with the subsequent final phase of data collection. Table 2 shows the profile of respondents.

The cut-off point for factor loading is 0.55 based on a sample size of 100 [24]. All measures loaded onto the hypothesized constructs although for perceived awareness, measures loaded onto two factors. Because the two factors were correlated, they were regarded as a similar construct.All measures Cronbach's alpha (α) were greater than 0.70 indicating reliable measures A correlation analysis was consequently run using summated scale (Table 4).

Correlation is significant at the 0.01 level (2-tailed)

Based on Table 4, all factors under investigation are positively correlated to each other.

4 Conclusion

The exploratory research sets out to answer two research questions: (1) What is the acceptance of MyRAM and CAPA among IT professionals? (2) Do subjective norm, perceived awareness and perceived importance correlate to risk assessment framework acceptance? Consequently, 12 hypotheses were proposed and the results show that all hypotheses were supported.

In answering the first research question, using descriptive analysis, the results suggest that IT professionals at the software company had positive perceptions toward acceptance of risk assessment framework. All measures of risk framework acceptance were valid and internally consistent in the context of Malaysian software development environment. Further, using correlation analysis there is evidence to suggest that as IT professionals perceive usefulness of the risk assessment framework, they will have intention to use it at their workplace. Besides, they perceive that the framework is easy to comply to. Owing to its ease of compliance, they are likely to see it as being useful to them.

In answering the second research question, the results of factor analysis and reliability analysis similarly suggest that all measures for subjective norm, perceived importance, perceived awareness perceived usefulness, perceived ease of compliance and intention to use were valid and reliable. There is evidence to support that people who matter to IT professionals at the workplace will promote the professionals' acceptance of the risk assessment framework. With awareness and perception of importance of the assessment framework, it may be inferred that they are likely to use it.

The TAM and TRA have been around for more than two decades. Yet they have shown the ability to explain the context of IT professionals' acceptance of risk assessment framework that have been implementedsince the last two years. This sheds new light in its application amidst new business models, explosive growth of the Internet, new business focus of software companies and complexities that have surfaced out of innovations.

The findings lend practical support to software companies desirous of implementing innovations at the workplace. To begin with, companies may consider specific awareness programs for employees that emphasize on the importance of such risk assessment methodology as a discipline. Only when employees are aware and perceive its importance, are they likely to accept it. As employees look up to others for personal gratification, companies may consider developing a culture where employees use others as a reference point in adopting innovations.

Limitations exist for the research. The data was collected on a convenient basis at a particular software company and in Malaysia. Future research may explore other companies and in countries other than Malaysia.

Acknowledgement

The researchers express utmost appreciation to all research participants of the company.
