A GRAPHICAL COST-SCREEN TECHNIQUE FOR CARBON MANAGEMENT

BUSARI BOLAJI IBRAHIM

A dissertation submitted in partial fulfilment of the  
Requirements for the award of the degree of  
Master of Engineering (Chemical)

Faculty of Chemical Engineering  
Universiti Teknologi Malaysia

JULY 2013

*Dedicated to the gentle soul of my late father AlhajiAbdulkadir Oba Busari*

## ACKNOWLEDGEMENTS

First and foremost, I would like to express my utmost appreciation and biggest gratitude to my dissertation supervisor, Prof. Dr. Zainuddin AbdulManan and my dissertation co-supervisor, Associate Prof. Dr. Sharifah Rafidah Wan Alwi for their myriad constructive comments and unwavering support to the completion of this research. Their guidance and encouragement are gratefully acknowledged.

Besides that, I hope to convey my countless gratitude to my valuable and dedicated wife, Hajia Rasheedat Ojuolape and my children, Sharaf'deen, Mufihdat, Musharaf and Abdulkadir for their patience throughout my program.

Other than that, I wish to express my acknowledgements to Alhaji Engr. Sirajo Lawal, Alhaji Engr. Dr. R.O Yusuf, and Dr MKA Abdul Rahman for providing valuable and useful information while preparing my dissertation.

Last but not least, I would like to take this golden opportunity to thank my golden mother Alhaja Khadijah Busari for her unlimited support and encouragements. Also, I wish to express my great appreciation to my siblings' juniors and seniors, my step mother Alhaja Kudirat Busari, close friends Sheikh Nma, Ismail, Bolaji, Sulaiman, Sakaki, Alfa Fatai, Abdulkareem Ibrahim (Alfa-kaa) and other unmentioned parties who have, directly and indirectly, providing their sincere guidance and support to the completion of my research. My father, my mentor, my spiritual-guidance, my pride, my valuable golden and diamond.... Alhaji. Sheikh. (prof). Sharaf'deen Saadudeen Ajara (RTA) thank you very much for always been there for me.

## ABSTRACT

Research involving carbon management has received increased attention over the last decades, due to the threat posed by global warming and increases in the atmospheric Green House Gas (GHG) emission. Improving energy efficiency, use of renewable energy and carbon dioxide (CO<sub>2</sub>) capture and storage are among the proposed methods for carbon management in the industrial sectors. Previous researchers have used carbon emission pinch analysis (CEPA) techniques to plan for carbon emission in the industry. But the cost effectiveness of the techniques has not been verified. This research is aimed at developing a graphical cost-screening technique for the CO<sub>2</sub> emission reduction planning in an industrial site. This method employs the carbon management hierarchy (CMH) as a tool to guide CO<sub>2</sub> emission reduction planning. It also extends the Systematic Hierarchical Approach for Resilient Process Screening (SHARPS) graphical cost-screening technique that was developed for water system to guide and screen design options involving process changes in order to obtain a cost effective system that meets a given CO<sub>2</sub> emission target. Application of the SHARPS screening techniques has successfully achieved the final cost effective minimum CO<sub>2</sub> emission target for a stationary site with TPP<sub>set</sub> (Total payback period set by designer) of 2 years, targeting 29.12 tons/hr of fresh CO<sub>2</sub> and 16.74 tons/hr of CO<sub>2</sub> emission prior to design. Using the predesign cost estimate method, the system needs approximately a net capital investment of USD 556.21 million, to give a net annual savings of USD 333.7 million with a total payback period of approximately 18 months.

## ABSTRAK

Kajian melibatkan pengurusan Karbon telah menerima perhatian yang meningkat sejak beberapa dekad, berikutan daripada ancaman yang ditimbulkan oleh pemanasan global dan peningkatan pembebasan Gas Rumah Kaca atmosfera. Meningkatkan kecekapan tenaga, penggunaan tenaga boleh diperbaharui dan penangkapan CO<sub>2</sub> dan penyimpanan adalah antara kaedah yang dicadangkan dalam sector industri. Penyelidik yang terdahulu telah menggunakan kaedah Analisa 'Picit' Pembebasan Karbon (CEPA) untuk merancang pembebasan karbon dalam industri. Namun, kecekapan kos teknik tersebut tidak disahkan. Kajian ini bertujuan membina satu kaedah grafik penyaringan kos untuk perancangan mengurangkan pembebasan CO<sub>2</sub> dalam tapak industri. Kaedah ini menggunakan hierarki pengurusan karbon sebagai alat panduan dalam perancangan mengurangkan pembebasan CO<sub>2</sub>. Ia juga memanjangkan teknik grafik penyaringan kos Pendekatan Hierarki Sistematis untuk Penyaringan Proses Berdaya Tahan (SHARPS) yang telah dibina untuk sistem air untuk panduan dan pilihan rekabentuk penyaringan melibatkan perubahan proses untuk mencapai satu sistem kos cekap yang memenuhi target pembebasan CO<sub>2</sub> yang ditetapkan. Aplikasi teknik saringan SHARPS telah mencapai kecekapan kos minima target pembebasan CO<sub>2</sub> akhir bagi tapak tersebut dengan TPP set (Jumlah tempoh pulangan yang ditetapkan oleh pereka) 18 bulan, menyasarkan 29.12 tan/jam CO<sub>2</sub> barudan 16.74 tan/jam pembebasan CO<sub>2</sub> sebelum rekabentuk. Menggunakan rekabentuk kawal bagi teknik anggaran kos, system ini memerlukan anggaran pelaburan modal bersih sebanyak USD 556.21 juta, untuk member simpanan tahunan bersih sebanyak USD 333.7 juta dengan jumlah tempoh pulangan kira-kira 18 bulan.

## **CHAPTER 1**

### **INTRODUCTION**

#### **1.1 Introduction**

Awareness of rising carbon dioxide (CO<sub>2</sub>) emission and possible ways to reduce them has captured the attention of the industrial sector. An increasing number of environmental, political, and social drivers are placing pressure on industry to determine the most viable and cost effective measures to limit their impact on climate change. Power generators are the highest point source emitters of CO<sub>2</sub> and will be among the most affected by future climate change regulations. Other industries like petroleum refining, cement production and steel manufacturing will likely need to adapt CO<sub>2</sub>emission management in future decisions and operation strategies.

Masjuki *et al.* (2002) explained emission as a process of energy utilization especially the emissions trial activities produced a huge effect on the environment that influences human health, organization growth, and climatic changes. In the near future, the energy consumption is expected to rise especially in developing countries, this is as a result of the rapid transformation in the industrial sector in recent times which consequently lead to massive release of pollutant to the environment causing harmful effect on environment and human health(Oh, 2010). The major increase in GHG is attributed largely to CO<sub>2</sub> emission as the main gas leading to global warming and climate changes.

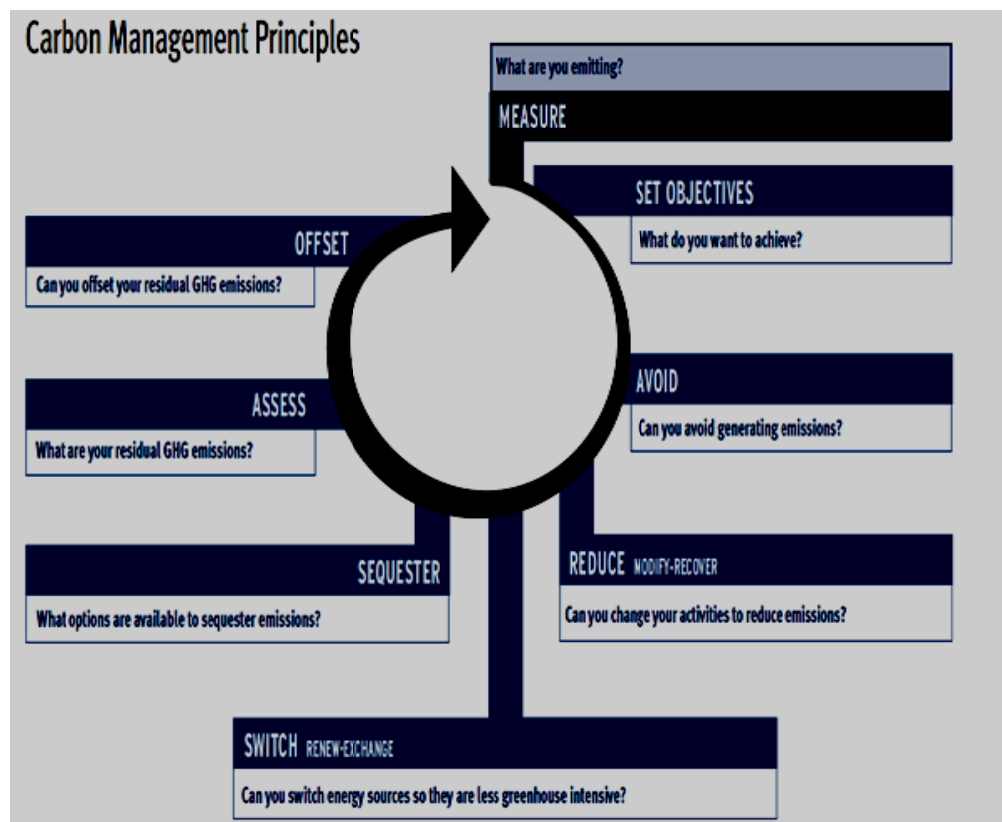

Sabooriet *al.* (2012) reported that, greater average air and ocean temperatures, extended melting of snow and ice and rising global average sea level are some profound proofs of global warming. IPCC(2007) predicted the rise in the global temperature and sea level of between 1.1°C to 6.4°C, 16.5cm to 53.8cm respectively by 2100. The amount of world energy demand contributed by fossil fuel is greater than 80% of the world energy demands are from fossil fuel which gives rise to increases in CO<sub>2</sub> concentration in atmosphere and contribute to global warming. CO<sub>2</sub> emission coefficients for various sources and corresponding energy conversion units are presented in Table 1.1.

**Table 1.1** :Carbon emission coefficients for different fuel sources and energy conversion units. (Adapted from Bousteet *al.*, 1979;Fluck 1992).

Fuel (source/ energy unit)	Equivalent carbon emission (kgCE)
One kg of fuel	
Diesel	0.94
Coal	0.59
Gasoline	0.85
Oil	1.01
LPG	0.63
Natural gas	0.85
Units	
Million calories(mcal)	$93.5 \times 10^3$
Gigajoule	20.15
BTU	$23.6 \times 10^6$
Kilowatt hour (kWh)	$7.25 \times 10^2$
Horsepower	$10^2$

The research involving carbon management has received increased attention over the last decades, due to the threat posed by global warming and increases in the atmospheric GHG emissions. Improving energy efficiency, use of renewable energy, and CO<sub>2</sub> capture and storage are among the proposed methods for carbon management in the industrial sector. Figure 1.1 shows the typical carbon management principles for measuring (Greenhouse gas) GHG emissions. The principles set out a framework for measuring GHG emissions. In practise, the framework can be applied through an iterative process. Depending on how far advance the industrial sector is in managing CO<sub>2</sub> emission. The first cycle through the principles may just enable identification of opportunities for CO<sub>2</sub> emission management. The second cycle can then be used to confirm objective and develop a strategy that optimizes CO<sub>2</sub> emission management.

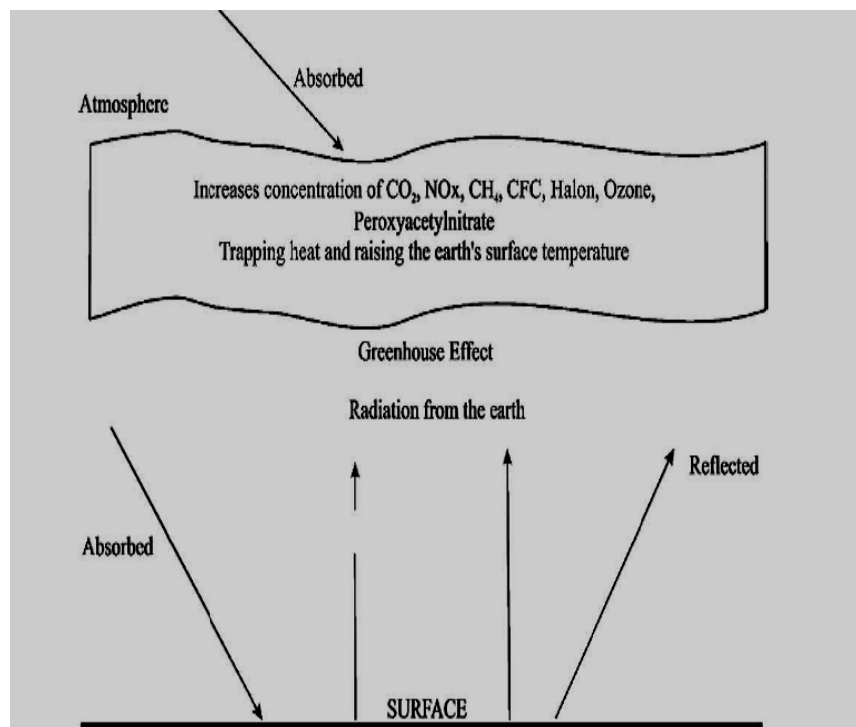

**Figure 1.1** Carbon management principle frame work for measuring GHG emission (EPA, 2007)

Munir *et al.*(2012) have established a viable tool through the use of process integration to reduce amount of CO<sub>2</sub> emission released to the atmosphere from industrial site and contributed to the emission reduction target. The aim of this work is to apply SHARPS techniques as a cost-screen tool guided by CMH to graphically design a cost effective minimum CO<sub>2</sub> emission target for an industrial site subjected to a desire payback period.

## 1.2 Research Background

Carbon management involves the measurement and management of the six greenhouse gases that are covered under the Kyoto protocol. The increasing concentration of GHG emission such as carbon dioxide (CO<sub>2</sub>), methane(CH<sub>4</sub>), nitrous oxide (N<sub>2</sub>O), sulphur hexafluoride (Sf<sub>6</sub>), Hydro fluorocarbons (HFCS), and Perfluoro carbons (PFCS) in the atmosphere is acting to trap heat radiation from the Earth's surface and is raising the surface temperature of the Earth (Dincer, 1998). The figure 1.2 showed a schematic representation of this global climate change problem.

**Figure 1.2** A schematic illustration of GHG effect (Dincer, 2000)

The principal gas leading to increases in GHG is CO<sub>2</sub> that attributed to the global warming and climate changes (The World Bank, 2007). The transformation of the economy from agriculture based to industrial level over the last three decades has elevated Malaysia to be the highest emitter of CO<sub>2</sub> among the South East Asian countries (Muiset *al.*, 2010). There is a 221% increase in CO<sub>2</sub> emission in Malaysia from 1990 – 2004 (Muiset *al.*, 2010). This has called the attention of Malaysia government to intensify their effort to reduce the CO<sub>2</sub> emission by 40% from 2005 level by 2020 subjected to financial aids from developing countries. The pledge was made in 2009 at the UN conference of parties in Copenhagen, Denmark by the Prime Minister Datuk Seri Najib Tun Razak. (Malaysia Digest.com 2009).

There have been extensive works on the best approaches to drastically minimize the amount of CO<sub>2</sub> emission from industrial process to achieve CO<sub>2</sub> emission reduction targets and reduce the impact of CO<sub>2</sub> emission on climate change. The work of (Park *et al.*, 2009) investigated the possibility of reducing CO<sub>2</sub> emissions in Korean petroleum refinery through the new energy saving technology and CO<sub>2</sub> mitigation. The work used five new technologies, which are Hybrid SD-Leap Mode, Crude Oil Distillation Unit (CDU), Light Gas Oil Hydro sulfurization Unit (LGO HDS), Vacuum Residue Hydro-Desulfurization (VR HDS) Process. The energy consumption and CO<sub>2</sub> emission of the nation, particularly from the industrial sector were estimated using the hybrid SD-LEAP model. The model predicted that, in the year 2030 the new technologies will cause 0.048% CO<sub>2</sub> reduction nationally and 0.109% reduction in the industrial sector. (Munir *et al.* 2012) introduced a holistic CO<sub>2</sub> emissions planning framework based on the Pinch Analysis graphical approach for CO<sub>2</sub> emission reduction. They plotted CO<sub>2</sub> source against CO<sub>2</sub> demands, and investigated some process modification options that can lead to CO<sub>2</sub> emission reduction targets for an industrial site.

This study extended the application of SHARPS technique as a cost screening tool to achieve the cost effective minimum CO<sub>2</sub> emission reduction target, considering all the process modifications guided by CMH. The net capital investment

(USD) will be plotted against the net annual savings (USD/yr). The slope of the plots represents the payback period for each process modification options.

### 1.3 Problem Statement

Over the past decades the main concern has focused on “end of pipe” treatment as an approach for CO<sub>2</sub> emission reduction such as CO<sub>2</sub> capture and storage (CCS), CO<sub>2</sub> injection in enrich oil recovery (EOR) among others. CO<sub>2</sub> emission reduction by process integrationbased on the Pinch Analysis approachlaterbecomespopular, being a viableinsight-based technology for CO<sub>2</sub> emission planning and reduction that is easy to understand and apply. Alongside development of the insight-based approaches, several works on CO<sub>2</sub> emission planning and minimisation using the mathematical programming approach have emerged. The mathematical techniques are however typically rigorous, and the mathematical equations are not easy to set up. This makes them less popular especially among the industrial practitioners. In this work the SHARPS technique has been extended as a costing tool to design a system to achieve the cost effective minimum CO<sub>2</sub> emission. The total payback period will be obtained by plotting net capital investment (USD) against the net annual savings (USD/yr) covering all levels of the carbon management hierarchy (CMH), SHARPS allow the total payback period to be evaluated subject to the desired payback period set by a designer. The problem statement can then be summarized as;

Given a process plant with several sources of CO<sub>2</sub> emission, it is desired to design a system to achieve the cost effective minimum CO<sub>2</sub> emissions for an industrial plant using the extended Systematic Hierarchical Approach for Resilient Process Screening (SHARPS) technique. SHARPS will be used to screen cost-effective process modification options that will be explored using carbon management hierarchy as a guide subject to a desired payback period set by a designer.

#### **1.4 Objective of Study**

The objective of this research work is to extend the application SHARPS graphical cost-screening tool that was developed for water system, and adopt it as a cost-screening tool to achieve a cost effective minimum CO<sub>2</sub> network design guided by CMH in the process changes.

## 1.5 Scope of Study

At the end of the study, a graphical cost-screen technique for carbon management will be developed by extending the SHARPS graphical cost-screen tool that was developed for water system. Tasks to be accomplished for achievement of study objectives include:

- Data collection which includes flow rate and concentrations of sources of gas streams containing CO<sub>2</sub>, then flow rates and concentrations of CO<sub>2</sub> demand streams.
- Extend the application of SHARPS graphical cost-screening tool for carbon emission planning. It can be achieved by plotting the net capital investment (USD) against the net annual saving covering all CMH. The gradient of the plot represent the payback period for process changes. The steepest positive gradient shows the most expensive scheme per unit CO<sub>2</sub> emission reduction. The total payback period will also be obtained by draw a straight line connecting the starting point and end at the end point of the IAS plot.
- The case study application of the graphical cost effective minimum CO<sub>2</sub> emission network design is still using the same case study of previous work of (Muniret *al.* 2012).

## 1.6 Significant of study

The main contribution of this study is to extend the application of SHARPS graphical cost-screen tool used in water management system and adopt it to achieve a graphical cost effective minimum CO<sub>2</sub> emission network design for an industrial site.

## 1.7 Outline of the dissertation

This research project dissertation consists of six chapters. **Chapter 1** gives an overview of global and local CO<sub>2</sub> emission management issues, problem statement, objective and scope of the study which aim at extend the application of SHARPS technique as a costing tool for cost effective minimum CO<sub>2</sub> emission reduction target network design.

**Chapters 2** Provide a literature review presented in this work. The development of research on CO<sub>2</sub> emission reduction target and network design techniques using mathematical programming, optimal planning system, and pinch analysis are reviewed. The cost of CO<sub>2</sub> capture is also discussed in this chapter.

**Chapter 3** Presents a detail methodology of this study to achieve the research objective. It consists of the technique to design a cost-effective minimum CO<sub>2</sub> emission reduction network to achieve a desired payback period set by a designer or plant owner.

**Chapter 4** Presents the discussion of the results on implementation of the developed methodology.

**Chapter 5** presents the conclusion and recommendation part of the work.
