

COMPUTATIONAL MODELLING AND SIMULATION OF BIOMAGNETIC  
FLUID FLOW IN A STENOTIC AND ANEURYSMAL ARTERY

NURSALASAWATI BINTI RUSLI

A thesis submitted in fulfilment of the  
requirements for the award of the degree of  
Doctor of Philosophy (Mathematics)

Faculty of Science  
Universiti Teknologi Malaysia

MARCH 2013

TO MY BELOVED HUSBAND, MOM, DAUGHTERS AND FAMILY

## ACKNOWLEDGEMENTS

First of all, thanks to Almighty Allah S.W.T for graciously bestowing me the perseverance to undertake this research. I sincerely have to thank all those who have supported and helped me writing this report. I wish to express my deepest gratitude to my supervisors, Professor Dr. Norsarahaida Saidina Amin, Dr. Airil Yasreen Mohd Yassin and Dr. Ahmad Kueh Beng Hong whose valuable time, expertise and guidance have been critical to my success.

I also would like to extend my sincere appreciation to all my friends who kindly provided valuable and helpful comments in the preparation of the thesis, and to those who have involved directly or indirectly in the preparation of this thesis, whom I have not mentioned above. Special thanks to Erwan Hafizi Kasiman for his willingness to be my *sifu*.

I wish to express deep appreciation and gratitude to Assoc. Prof. Dr. Sasa Kenjeres from Delft University of Technology, The Netherlands for fruitful discussions. Of course, special appreciation goes to two important institutions which have supported me, Universiti Malaysia Perlis (UniMAP) and Kementerian Pengajian Tinggi (KPT). Special thanks to my Dean and ex-Dean, Assoc. Prof. Dr. Abdul Wahab Jusoh and Assoc. Prof. Abdull Halim Abdul for their support and understanding throughout this study. I also deeply thank my parents and my family for their encouragement and patient support given in the preparation of this work.

To my husband, Muhamad Rasyidi Husin, for providing the necessary atmosphere of understanding and support during untold amount of hours at home required for writing this thesis. To my children, Husna, Nabilah, Hana and Danial, for your understanding and taking too much time to complete this research. To all of you, I say a most heartfelt thank you.

## ABSTRACT

This thesis is concerned with the development of mathematical models for the computation and simulation of biomagnetic fluid flow in either a stenosed or aneurysmal artery in the presence of non-uniform magnetic fields. The mathematical models take into account blood rheology where blood behaves as a magnetic fluid due to the complex interaction of intercellular protein, cell membrane and haemoglobin. The present study involves steady three-dimensional biomagnetic fluid flow and mass transfer through a horizontal cylinder. Numerical solutions obtained through a finite volume method shows that the magnetisation force has an effect on the fluid concentration and exerts a greater influence on the secondary flow motions compared to that caused by the Lorentz force. Earlier studies allow only Lorentz force due to uniform magnetic fields but neglect the effect of magnetisation force. Here, a modified finite difference method has also been designed specifically to study separately the effect of magnetisation force, Lorentz force or both, on a steady two-dimensional channel flow. It is observed that a distorted asymmetric flow profile is presented near the magnetic source and that the Lorentz force gives little influence to the flow behaviours, vindicating previous proposition that the Lorentz force need not be considered in the model of biomagnetic fluid flow.

## ABSTRAK

Tesis ini berkaitan pembangunan model matematik untuk pengiraan dan simulasi bagi aliran bendalir biomagnet di dalam arteri berstenosis atau beraneurisma di bawah pengaruh medan magnet tak seragam. Model matematik ini mengambil kira reologi darah bahawa darah bertindak sebagai suatu bendalir magnet disebabkan oleh interaksi kompleks antara sel protein, sel membran dan hemoglobin. Kajian ini melibatkan aliran mantap tiga matra bagi bendalir biomagnet melalui silinder mendatar dengan pemindahan jisim. Penyelesaian berangka yang diperolehi menggunakan kaedah isipadu terhingga menunjukkan daya pemagnetan memberi kesan kepada kepekatan bendalir dan mempunyai lebih pengaruh terhadap aliran sekunder berbanding aliran yang teraruh oleh daya Lorentz. Kajian sebelum ini tidak mempertimbangkan kesan daya pemagnetan, sebaliknya hanya mempertimbangkan daya Lorentz yang terhasil daripada medan magnet seragam. Di sini, kaedah beza terhingga telah diubahsuai khususnya untuk mengkaji secara berasingan kesan daya pemagnetan, daya Lorentz atau kedua-duanya terhadap aliran mantap dalam saluran dua matra. Hasil kajian menunjukkan profil aliran tak simetri berubah berhampiran sumber magnet, dan daya Lorentz pula mempunyai pengaruh yang kecil kepada kelakuan aliran. Keputusan ini mengesahkan hujah sebelum ini bahawa daya Lorentz boleh diabaikan bagi model aliran bendalir biomagnet.

## LIST OF SYMBOLS AND ABBREVIATIONS

### SYMBOLS:

$\rho$	-	Density
$\bar{u}$	-	Velocity vector
$\nabla$	-	Gradient operator
$\frac{D}{Dt}$	-	Material derivatives
$T$	-	Temperature
$Sh$	-	Sherwood number
$Sc$	-	Schmidt number
$\vartheta$	-	Diffusion constant
$\Delta C$	-	Reference concentration difference
$c$	-	Concentration
$\Phi$	-	Dissipation function
$\sigma$	-	Stress
$\tau$	-	Viscous stress tensor
$P$	-	Pressure
$\mu$	-	Dynamics viscosity
$\nu$	-	Kinematic viscosity
$\chi$	-	Magnetic susceptibility
$M$	-	Magnetisation
$\mathcal{L}$	-	Differential operator
Re	-	Reynolds number
$\bar{\beta}$	-	Thermal expansion
$\bar{g}$	-	Acceleration due to gravity
$E_c$	-	Eckert number
$\varepsilon$	-	Temperature number

$Mn_F$	-	Magnetic number due to FHD
$Mn_M$	-	Magnetic number due to MHD
$\mathbf{F}^L$		Lorentz force
$\mathbf{F}^M$		Magnetisation force
$\bar{\sigma}$	-	Electrical conductivity
$\bar{c}_p$	-	Specific heat
$k$	-	Thermal conductivity
$\bar{h}$	-	Reference length
$\bar{u}_r$	-	Reference velocity
$\bar{H}_r$	-	Reference magnetic field intensity
$\bar{H}$	-	Magnetic field gradient
$\phi$	-	Electrical potential
$C_f$	-	Skin friction coefficient
N	-	Stuart number

#### ABBREVIATIONS :

CFD	-	Computational fluid dynamics
BFD	-	Biomagnetic fluid dynamics
FDM	-	Finite difference method
FVM	-	Finite volume method
FEM	-	Finite element method
MDT	-	Magnetic drug targeting
FHD	-	Ferrohydrodynamics
MHD	-	Magnetohydrodynamics
SIMPLE	-	Semi-Implicit Method for Pressure-Linked Equations
TDMA	-	Tri-Diagonal Matrix Algorithm
ECG	-	Electrocardiogram
LDL	-	Low density lipoprotein
WSS	-	Wall shear stress

# CHAPTER 1

## INTRODUCTION

### 1.1 Introduction

Blood is essential in maintaining life. It transports oxygen and nutrients to all parts of the body, relays chemical signals and moves metabolic waste to the kidneys for elimination. Despite more than 150 years of closed study, a concise, predictive model of blood flow is still of far reaching. A quantitative model of blood flow is important not only as it relates to clinical diagnosis of disease, but as an integral component of models of more complex structures. In this introductory chapter, some physiological background is provided in order to pave the way for the mathematical modelling and numerical simulations to be developed in later chapters.

To date, numerous mathematical models have been developed to describe blood flow in the circulatory system (Mahapatra *et al.* (2002), Midya *et al.* (2003), Maikap *et al.* (2005), Layek and Midya (2007), Chakravarty *et al.* (2007)). Following such a tradition but looking at different aspect, this thesis adopts the biomagnetic fluid model in representing the blood flow. A biomagnetic fluid is defined as a fluid that exists in a living creature and its flow is influenced by the presence of a magnetic field. The main reason in choosing this model to describe blood flow comes from the fact that blood behaves as a magnetic fluid (Tzirtzilakis, 2005). Due to the complex interaction of the intercellular protein, cell membrane and the hemoglobin, a form of iron oxides presents at a uniquely high concentration in the mature red blood cells (erythrocytes). Its magnetic property is affected by factors such as the state of oxygenation (Higashi *et al.* 1993).

During the last decades, extensive research has been done on the fluid dynamics of biological fluids in the presence of magnetic field. Numerous useful applications have been proposed in bioengineering and medical sciences (see Ruuge and Rusetski (1993), Plavins and Lauva (1993), Haik *et al.* (1999)). Among them are the development of magnetic devices for cell separation, targeted transport of drugs i.e. using magnetic particles as drug carriers, magnetic wound treatment and cancer tumor treatment, reduction of bleeding during surgeries and provocation of occlusion of the feeding vessels of cancer tumors and development of magnetic tracers.

It is imperative to acknowledge that mathematical modelling and numerical simulations provide many important insights on the underlying interactions between blood flow and magnetic field, some of which are not directly assessible through experimental investigation. Computational simulations make possible the study of the feasibility of a medical technique before entering clinical trials, and simulations are useful for investigating the influence of various factors independently (Haverkort and Kenjeres (2008), Haverkort *et al.* (2009)). Since the human blood is slightly electrically conductive, it is important to formulate a mathematical model that mimics properly the effects of magnetisation and Lorentz force on the blood flow (Kenjeres and Opdam, 2009). The application of biomagnetic fluid will be considered in this research because the model is more realistic from the physiological point of view.

## 1.2 Problem Statement

Computational fluid dynamics (CFD) occupies one of the key physical disciplines that involve the description of fluid flow in terms of mathematical models which comprise convective and diffusive transports of matters. New techniques are needed when problems in real environments get more difficult and complex. Such complexities are encountered especially when the behavior of fluid in motion is no longer governed by the Navier-Stokes equations alone. In considering more realistic behaviour of the flow, such as biomagnetic fluid model in this study, other effects must be considered and this usually results in coupled partial differential equations.

One of the major difficulties in solving such a coupled problem is the handling of pressure terms in which singularity occurs. Having stated aforementioned matters, this study is therefore very general nature in regard to interactions between mathematical model, numerical simulation and blood flow behaviour in oversimplified geometries (artery is never a perfectly circular straight tube). Even so, we put concentration on the effects of two-dimensional and three-dimensional biomagnetic blood flow models when being imposed with non-uniform magnetic field. There are several issues pending to be addressed, all of which are stated in the followings. What are the effects on blood flow characteristics of anomalous geometry in stenosis and aneurysm compared to normal arteries in presence of magnetic field? What are the severities of the oxygen distribution along the artery for both geometries? What are the effects of aforementioned cases under the influence of non-uniform magnetic field? What are the effects on blood flow patterns when only magnetisation force is imposed? What happens to the flow when magnetisation and Lorentz forces are imposed? These research questions constitute the main concern of the present thesis.

### **1.3 Objectives of Research**

The main concern of current study is to investigate the two-dimensional and three-dimensional blood flow through an artery by solving the following problems:

1. To investigate the blood flow patterns considering a three-dimensional channel flow in horizontal cylinder, cylindrical geometry with significant narrowing (mimicking stenosis) and cylindrical geometry with significant swelling (mimicking aneurysm) allowing magnetisation and Lorentz forces.
2. To determine the effect of mass and flow transport phenomena associated with disease on geometries stated in (1).
3. To derive and solve Navier Stokes differential equation allowing magnetisation force description using finite difference method considering a two-dimensional channel.

4. To derive and solve Navier Stokes differential equation allowing magnetisation and Lorentz forces description using finite difference method considering a two-dimensional channel.

#### **1.4 Scope of Research**

This study considers the nonlinear, steady, two-dimensional and three-dimensional blood flows through an artery in the presence of magnetic field. In addition, the symmetric and three-dimensional cylinder, stenotic and aneurysmal blood flows through an artery are investigated. It is imperative to emphasize also that this study only considers single horizontal flow without branching effect, treating all material properties as constant. In addition to the neutral conditions (0 Tesla), the investigated strengths of magnetic field include 5 Tesla and 10 Tesla. The finite volume method (FVM) will be used as the numerical technique for three-dimensional models. For two-dimensional modelling, a modified numerical algorithm based on the finite difference method (FDM) will be adopted.

#### **1.5 Significance of Research**

The significance of the study can be stated as follows:

1. To present more realistic mathematical models to interpret and enhance the understanding of blood flow characteristics under stenotic and aneurysmal conditions through mathematical behaviour.
2. The establishment of new numerical techniques will pave the way for the solution of more difficult bio-fluid and mathematical problems.

3. For diagnostic purposes, this study would help molding the fundamental understanding of bio-fluid behaviour and contribute to the advancement of medical science.
4. Development of simulation and visualization packages of real-time solution for application in medicine for physicists and biomedical engineers.

## **1.6 Outline of the Thesis**

This thesis is divided into seven chapters including this introductory chapter. Chapter 1 presents some general introduction, research background, objectives, scope and significance of research. All the problems in this study are based on the Navier Stokes equations which is associated with varying magnetic field. Chapter 2 contains the general literature review on the significance of this study. Considered problems will be discussed in four chapters, namely Chapters 3 through 6. All of these problems are solved numerically using either the finite volume method or finite difference method.

Chapter 3 discusses the blood flow patterns allowing magnetisation and Lorentz forces through a horizontal cylinder, cylindrical geometry with significant narrowing (mimicking stenosis) and cylindrical geometry with significant swelling (mimicking aneurysm). This chapter is divided into nine main sections, content of which includes the introduction, literature review, governing equations, numerical model description, numerical method, verification, steady blood flow through an artery subjected to the external magnetic field, flow distribution of velocity in two-dimensional view and conclusions. The discussion is focused on the effects of blood flow patterns when being imposed with different strengths of magnetic field which is 0 Tesla, 5 Tesla and 10 Tesla. The presentation of problem takes the form of a three-dimensional channel flow solved using a finite volume method.

In Chapter 4, problem related to the effect of mass and flow transport phenomena will be discussed. This problem is an extension from the first problem (Chapter 3) which also involves magnetisation and Lorentz forces. This chapter contains six sections. They are introduction, literature review, governing equations, numerical method, results and discussions and conclusions. In this chapter, the discussion concentrates on the effect of mass and flow transport phenomena associated with disease on geometries stated in Chapter 3 when exposed to various magnetic field values.

Chapter 5 explains a two dimensional channel flow allowing magnetisation force. This chapter is divided into seven sections: the introduction, literature review, governing equations, numerical method, verification, results and discussions and conclusions. A modified finite difference scheme based on staggered grid will be used to derive and solve Navier-Stokes differential equation. Three benchmark cases were considered for verification, i.e. lid driven cavity flow, Pouiselle flow and backward facing step flow. The discretization of the Navier Stokes equations allowing magnetisation force description in the numerical computation part is given afterward. This method has been found to be suitable and flexible to deal with varying magnetic field i.e. magnetisation force.

Finally, the last problem is discussed in Chapter 6 which concentrates on the effects of Lorentz force when associated with magnetisation force from Chapter 5. This chapter is divided into seven sections: the introduction, literature review, governing equations, numerical method, verification, results and discussions and conclusions. In this chapter, Navier-Stokes differential equation allowing magnetisation and Lorentz forces description will be derived and solved using the same method as described in Chapter 5. The model verification and validation are carried out in terms of results comparison with the analytical solution of 2D Hartman flow. The final and concluding chapter, Chapter 7, contains some concluding remarks, summary of research as well as some suggestions for future research.
