

**THE EFFECT OF BALCONY ON THERMAL PERFORMANCE OF
HIGH RISE OFFICE BUILDING IN TROPICAL CLIMATE**

OMOYOLA TOLULOPE AYOKUNLE

A thesis submitted in fulfilment of the
requirements for the award of the degree of
Master of Architecture

Faculty of Built Environment
Universiti Teknologi Malaysia

FEBRUARY 2015

To:

My Beloved Father, Mother, Sisters and Brothers

ACKNOWLEDGEMENT

My deepest gratitude goes to my thesis main supervisor Prof Madya Dr. Abdullah Sani Bin Ahmad for his support, guidance and supervision throughout the period of my study. I am glad to be a student under his supervision because through him, I have learnt a lot of things academically and morally. I appreciate him so much for his effort in making this thesis a success. I would also like to extend my thanks to Dr Ismail for his engagement and advice during the period of study.

I would like to acknowledge the Federation of Malaysian Manufacturers (FMM), GDP Architect and the Malaysian Meteorological Department for providing the relevant information that assisted during the progress of the research.

My grateful thanks goes to Lin Yola for her help in advising and editing of my thesis, without you, the thesis would not have been a success. My thanks also come to Olutobi Ayegbusi for his advice, concern and support throughout the period of this thesis. My thanks also go to Aaron Osikhena, Eyinanabo Odogu, Hirda Khalida, Syaihan Khalida and Chandra for their accommodation, help and support throughout the period of writing this thesis. To all as mentioned above, may God Almighty reward each and every one more abundantly according to his riches in glory.

Finally, I would like to express my endless gratitude to my father, sisters and brothers for their support, advice, love and guidance throughout the period of study in Malaysia, may God bless each and every one abundantly.

ABSTRACT

The design of balcony has been incorporated into the design of high-rise residential buildings, but has not been well considered in commercial high-rise buildings such as a high-rise office building except for the bioclimatic high-rise buildings. Balcony, which is referred to as an efficient wind box, functions as a thermal control element in buildings by minimizing heat gain into the interior spaces, thus reducing the amount of energy used for cooling load in buildings. This research aims at investigating the effect of balcony on the thermal performance of the interior spaces of high-rise office building. Balcony with the depth of 1m, 1.5m, 2m, and 2.5m were investigated on the 1st, 15th, 25th and 40th floor level at the north, south, west and east orientation of high-rise office building. Cap Square high-rise office building which is situated in the tropical city of Kuala Lumpur was used as a case model. A computer simulation software (Ecotect) was used for the evaluation of the indoor air temperature of the high-rise office with and without the balcony. The investigation was observed during the office hours from 9am to 6pm on the 22nd of March, 22nd of June, 22nd of September and 22nd of December. The result revealed that, on the 22nd of March and the 22nd of June, the maximum reduction of 1.83°C and 1.75°C (respectively) was recorded on the 1st floor level at the west orientation with the balcony of 2.5m, while on the 22nd of September and the 22nd of December, the maximum reduction of 0.31°C was recorded on the 40th floor level at the west orientation with the balcony of 2.5m when the indoor air temperature of the high-rise office buildings with and without the balcony were compared. This study further revealed that, the balcony with the depth of 2.5m is recommended for the 1st, 15th and 25th floor level on the west, north and east orientation, while the balcony of either 2.0m or 2.5m is recommended for the 40th floor level on the south, west and east orientation of high-rise office building.

ABSTRAK

Reka bentuk serambi telah digabungkan ke dalam reka bentuk bangunan tinggi kediaman tetapi masih belum dipertimbangkan ke atas bangunan tinggi komersial seperti bangunan tinggi pejabat kecuali pada bangunan bioiklim tinggi. Serambi, seringkali disamakan sebagai kotak angin yang cekap berfungsi sebagai elemen kawalan haba dalam bangunan dengan meminimumkan penyerapan haba ke dalam ruang dalaman, sehingga, dapat mengurangkan jumlah tenaga yang akan digunakan untuk penyejukan bahagian dalaman bangunan. Kajian ini bertujuan untuk menyiasat kesan serambi terhadap prestasi haba daripada ruang bahagian dalaman bangunan tinggi pejabat. Serambi dengan kedalaman 1m, 1.5m, 2m, 2.5m telah disiasat pada tingkat satu, tingkat 15, tingkat 25 dan tingkat 40 di bahagian utara, selatan, barat dan timur bangunan tinggi pejabat. Bangunan tinggi pejabat 'Cap Square' yang terletak di bandar tropika Kuala Lumpur telah digunakan sebagai model kes kajian. Perisian simulasi komputer (*Ecotect*) telah digunakan bagi menilai suhu udara di bahagian dalaman bangunan tinggi pejabat dengan serambi dan tanpa serambi. Siasatan telah dilakukan dan diperhatikan ketika waktu pejabat antara jam 9:00 pagi hingga 6:00 petang pada 22 Mac, 22 Jun, 22 September dan 22 Disember. Hasilnya menunjukkan bahawa pada 22 Mac dan 22 Jun, penurunan maksimum sebanyak 1.83°C dan 1.75°C tercatat pada tingkat satu di bahagian timur, manakala pada 22 September dan 22 Disember, penurunan maksimum sebanyak 0.31°C direkod pada tingkat 40 di bahagian barat dengan serambi pada kedalaman 2.5m ketika udara dalaman bangunan tinggi pejabat dengan serambi dan tanpa serambi dibandingkan. Kajian ini mendedahkan bahawa, serambi dengan kedalaman 2.5m disyorkan bagi tingkat satu, tingkat 15 dan tingkat 25 di bahagian barat, utara dan timur, manakala serambi dengan kedalaman 2.0m atau 2.5m disyorkan bagi tingkat 40 di bahagian selatan, barat dan timur bangunan tinggi pejabat.

U-value	-	Thermal Conductance

LIST OF SYMBOLS

$(A, B, a, b, \alpha, \beta)$	-	Coefficients which depends on the geometric.
$(\rho \times c) a$	-	Heat capacity of air.
(β)	-	Solar altitude.
(ϕ)	-	Solar azimuth.
a	-	Surface absorptive.
ach	-	Numbers of times of the whole air volume of the space
A_i	-	Respective areas of the elements
B	-	Atmospheric extinction coefficient.
C	-	Contaminant concentration
C_e	-	Contaminant concentration at the ventilating exhaust.
C_f	-	Surface drag coefficient
C_n	-	Clearness number of the atmosphere.
$\cos \theta$	-	Extra-terrestrial irradiance on an inclined surface
$\cos \theta_z$	-	Extra-terrestrial irradiance on a horizontal surface.
C_s	-	Contaminant concentration at the supply.
E	-	Air distribution effect.
E_T	-	Equation of time.

F	-	Rectangular openings.
F_{ss}	-	The angle factor between the surface and sky
g	-	Acceleration due to gravity (ms^{-2}).
h_0	-	External surface heat transfer coefficient;
I	-	Striking solar radiation.
i and j	-	Zone in the path of ij.
I_b	-	Beam irradiance on a horizontal surface on earth.
$I_b^{\theta_y}$	-	Beam irradiance on an inclined surface on the earth.
I_{diff}	-	Diffuse sky radiation.
I_o	-	Apparent extra-terrestrial irradiance.
$I_o^{\theta_y}$	-	Extraterrestrial hourly radiation incident on an inclined
k	-	Von Karman's constant
L_{loc}	-	Longitude of the location in degree.
L_{std}	-	Standard meridian for local time zone.
LWR	-	Temperature drop due to long wave radiating to the sky.
n^{ij}	-	Flow exponent of path.
Nu	-	Nusselt number
ϕ	-	The parameters of ventilation performance (such as air temperature, air velocity and turbulence)
p	-	Air density
P_h	-	Depth of the horizontal element.
Pi and Pj	-	Total pressure

P_v	-	The depth of a vertical projection
Q	-	Heat loss.
q	-	Solar gain
Q_c	-	Conductive heat loss of a building.
Q_i	-	Heat gain.
Q_n	-	The air flow entering or leaving through each opening.
Q_{net}	-	Net heat need.
Re	-	Reynolds' number
S_h	-	Shadow height.
		surface oriented in any direction
S_w	-	Shadow width.
t	-	Wind shear stress
T_a	-	Outdoor air temperature.
$T_{in} - T_o$	-	The indoor - the outdoor temperature difference.
T_{in}	-	Indoor temperature.
T_{sa}	-	Sol -air temperature.
T_{sol}	-	Local solar time.
T_{std}	-	Local standard time.
$u(z)$	-	Airspeed at height z
UA	-	Heat loss coefficient.
U_{gl}	-	Value of glazed u value.
U_i	-	Respective values of the elements.
V	-	Airflow rates (in m^3/hr)
Vol	-	Changes in an hour.

z	-	Roughness parameter
β	-	Solar altitude angle above horizontal.
γ	-	Surface azimuth angles.
δ	-	Solar declination angle.
δ	-	Solar declination angle
θ	-	Incident angle.
θ_h and θ_v	-	Angle of incidence on horizontal and angle of incidence on vertical surfaces.
ϕ	-	Latitude of the location.
Ω	-	Profile angle.
ω	-	Solar hour angle.
ζ	-	Surface tilt angle.
$\Gamma_{\phi,\text{eff}}$	-	The effective diffusion coefficient

CHAPTER 1

INTRODUCTION

1.1 Introduction

Over the past decade, the architecture style in Malaysia had experienced a rapid transformation, which occurred as a result of rapid economic growth and industrialization in the country. The rapid growth had led to a rapid development which resulted in the transformation of the traditional and colonial buildings (which are virtually an eclectic architectural style) into a more creative and innovative architectural style which gave rise to the establishment of high-rise buildings in most of the vibrant cities in Malaysia. The erection of high-rise buildings have put Malaysia in the forefront of the developing countries as it symbolizes a fast growing economy and a sign of progress. Today, high-rise buildings in Malaysia serve the purposes of residential and commercial buildings. High-rise building is defined by Curl (2006) as a tall structure, which comprises of many floors. Emporis (2012) further defines high-rise as a building with at least a minimum of 12 floors and a maximum of 39 floors or a multi-story building within 35 to 100 meter. The Federal Emergency Management city of Chicago defined high-rise building as an existing structure, which consists of four different categories which are; high-rise buildings

over 780ft (288m) above the ground, 540ft (165m) above the ground, 275ft (84m) above ground and 80ft (24m) above ground. Thus, the researcher uses the definition by the Federal Emergency Management city of Chicago because it gives a clear variation of the possible height of high-rise buildings.

As revealed by Seung Bok Leigh, Bae and Ryu (2004); Pyoung Jik Lee et al., (2007); Myung Jun Kim and Ha Geun (2007); Chan and Chow (2010), high-rise residential buildings have been incorporated with the design of balcony, an important element of the Malay traditional house that has been incorporated into the design of the residential high-rise building in the tropical climate of Malaysia, (Ismail, 2007), but has not been incorporated into the design of conventional commercial buildings (such as the high-rise office buildings) except for the bio-climatic high-rise office buildings such as Menara Boustead (1987); Menara Mesiniage (1987-1992); IBM Plaza (1984-1987) and Menara UMNO (1996-1998) which was designed by the Malaysian architect, Ken Yeang.

As revealed by Ismail, (2007), high-rise office buildings in the tropical region of Malaysia consist of two typologies, which are; the conventional and the bioclimatic high-rise office buildings. As mentioned by Joo-Hwa Bay and Boon-Lay Ong (2004), conventional high-rise office buildings are the buildings that are designed with an international style and are built in an emotive forms that have ignored all aspects of tropical context in terms of climate, environmental as well as human needs and have made a self-expression and self-reference of aesthetics as a priority in the design. As mentioned by Olgyay and Olgyay, (1963) and Ken Yeang (1991), bioclimatic high-rise buildings (office) are the built forms that are configured in relations to the meteorological climate data of the locality (tropical climate).

Climatically, the approach of architectural design high-rise office building in the tropic is to achieve a sustainable design. The term sustainable design is defined

by Brundtland, (1987) as the means to meet the needs of the present without altering the ability to meet the needs of the future generations. Often sustainable design are mostly used interchangeably with green design, therefore, the United-States Green Building Council (2005) defined green design as the design and construction practices that significantly minimizes or eliminates the negative impact of buildings on the environment as well as the occupants. The sustainability concern in a tropical climate in the building industry is to design and build towards a more bioclimatic approach (Zakaria and Ismail, 2012). Bioclimatic design approach has been properly incorporated into low and medium rise buildings, but has not been well developed in high-rise buildings (such as office buildings) (Olgyay and Olgyay, 1963). Thus, in order to achieve a bioclimatic approach in high-rise office buildings, the sustainable issues of high-energy consumption must be addressed through passive strategies with the modification of the internal climate (Zakaria and Ismail, 2012).

In the tropical climate of Malaysia, the daily temperature is always high mostly during the daytime with an average temperature which ranges between 29°C and 34°C (Samirah and Kannan, 1997a) and a high relative humidity which ranges between 70% to 90% throughout the year (Daghigh, Sopian, and Moshtagh, 2009). Thus, high-rise buildings are exposed to most intensity solar radiation and penetrations (Sadafi et al., 2011) which results in the use of air conditioner in order to regulate the thermal condition within the indoor spaces to a satisfactory level. This strategy (air conditioner) of regulating the indoor comfort has resulted into high consumption of energy for cooling loads. Therefore, in order to derive an alternative strategy for controlling the thermal performance within the indoor spaces of high-rise office building, an element, which can maximize the effect of a thermal mass in such a way that it minimizes the indoor temperature, is needed. Therefore, a balcony, which is one of the elements of a sustainable approach (bioclimatic) in high-rise building (Ken Yeang, 1991), is introduced to high-rise office building.

Balcony is referred to as an efficient wind box which functions as a thermal control element in building by preventing heat gain into the interior spaces as well as maximizing the heat loss in a building (Ken Yeang, 1991). However, Oxford Dictionary (2000) defined a balcony as a platform enclosed by a wall with a balustrade or railing extending outside or inside the walls of a building. Mohsen and Oldham (1977); May (1979); Tzekakis (1983); Hammad and Gibbs (1983); Hothersall, Horoshenkov and Mercy (1996); Cheung, Chau and Ng (1997); Seung Bok Leigh, Bae and Ryu (2004); Pyoung Jik Lee et al. (2007); Myung Jun Kim and Ha Geun (2007); Chan and Chow (2010) have done research on how balcony can prevent traffic noise in high-rise residential building through the use of acoustic materials. Kwong Wing Chau and Siu Kei Wong (2004) and Cheung, Chau and Ng (1997) conducted research on how a balcony with a rectangular shape can add to the value of a residential apartment building. As mentioned by Seung Bok Leigh, Bae and Ryu (2004), balconies are categorized into 3 types, which are opened balcony, enclosed balcony and extended balcony. As revealed by Seung Bok Leigh, Bae and Ryu (2004), courtyard is one of the types of balcony categorized under an enclosed balcony; therefore, as mentioned by Zakaria and Ismail (2012), researches have been done with the use of rectangle shape of balcony in buildings. Elisabeth Gratia and Andre De Herde (2007), Zollner, Winter and Viskanta (2002), Till Pasquay (2004) and Hoseggen, Wachenfeldt and Hanssen (2008) research on the passive cooling strategies in office building with a double skin façade, however, based on the review; there have not been much of researches done on high-rise office building with the balcony. Therefore, as revealed by Ken Yeang (1991) that, in order for high-rise office building in hot and humid climate to reduce the effect of high solar radiation in the interior spaces, a deep recess space such as balcony must be introduced in the exterior façade of high-rise office building. As further revealed by Ken Yeang (1991), balcony in an office building functions as an emergency evacuation, a flexible zone for planting and landscaping, a space that permit for the extension of an executive space and a semi- enclosed transitional space for the users' of the building (office) to experience and enjoy the outside view of their external environment. Therefore, the research focuses on investigating the effect of a rectangular shaped

opened balcony on thermal performance in the interior spaces of the high-rise office building in a tropical climate.

1.2 Problem Statement

The sustainable issue, which is always highlighted in buildings, is the high consumption of energy (Zakaria and Ismail, 2012). Recent reports have shown that commercial high-rise buildings are one of the largest consumers of energy in tropical region. As revealed by Chirarattananon and Taweekun (2003), that the energy used in office buildings in Thailand consumed about 21% of the country's energy. As revealed by Yang, Joseph and Tsang (2008), the office buildings in China consume 10 to 20 times the energy used by residential buildings.

The Energy Commission in Malaysia (2007) also revealed that commercial buildings are the second largest user of the total energy consumed in the country after industry and transportation sector (as shown in Figure 1.1).

Figure 1.1: Energy used by different sectors in Malaysia

Source: Hussain, Nallagownden and Ibrahim (2011)

A study audit which was carried out by Saidur (2009) revealed that in office buildings, air conditioning consume about 57% of the main energy, followed by lighting which is 19%, lifts and pumps 18% and others 6% (as shown in Figure 1.2). The above review shows that, high-rise office building relies on the mechanical ventilation system (air conditioner) to create an artificial comfort in office buildings, thus, raising the cost of the cooling load of the users' spaces in the office buildings. As revealed by Bunn (1993), a 1°C reduction in temperature is equivalent to a 10% decrease in energy consumption. Therefore, this research focuses on the techniques of reducing the indoor air temperature in high-rise office building in the tropical climate of Malaysia by investigating on the best orientation and the importance of balcony on high-rise office building.

1.3 Research Objectives

The primary intention of this study is to investigate the impact of balcony on high-rise office building. In order to know how effective the impact of balcony is on high-rise office, the indoor air temperature in the interior spaces of high-rise office building with and without the balcony was investigated on. The objectives are as follows:

1. To investigate about the configurations of balconies on high-rise office buildings.
2. To investigate the depth of balcony that influences the thermal performance at the 1st, 15th, 25th and 40th floor level of the high-rise office building.
3. To investigate about the effect of balcony on the north, south, west and east orientation of the high-rise office building during the office hours (9am to 6pm).

1.4 Research Questions

The research questions give the bases of the problems to be solved. The research questions are as follows:

1. What are the configurations of balconies on high-rise office buildings?
2. What are the depths of balconies that influence the thermal performance at the 1st, 15th, 25th and 40th floor level of the high-rise office building?
3. What is the effect of balcony at the north, south, west and east orientation of the high-rise office building during the office hours (9am to 6pm)?

1.5 Scope and Limitation of Research

The scope of the research focuses on high-rise office buildings in the tropical climatic of Malaysia. The scope of the research is limited to the golden triangle area in Kuala Lumpur because a lot of high-rise buildings are located within the area. A high-rise office building called the Cap Square tower, which is situated at Jalan Munshi Abdullah in Kuala Lumpur, was selected as a case model. Cap Square Tower was selected because it fulfills the criteria of a tropical high-rise building as mentioned by Ken Yeang (1994); Kannan (1991) and Mineki Hattori (1984) in terms of the building shape (rectangular) and the position of the core location in the building, which is at the central of the high-rise office building. The building is designed with a curtain wall at the 4 sides of the façade and the case model high-rise office building is without balcony, but with exterior light shelves. In order to investigate about the effect of balcony on high-rise office building, a 3D model of the case model of the high-rise office building was modeled into two types; which are; the model with the balcony and the model without the balcony. Based on the review of previous researches as such Li et al. (2003); Hossam El Dien and Woloszyn, (2004); Tang (2010); Myung Jun Kim and Ha Geun (2007); and Pyoung Jik Lee et al. (2007), a rectangular form of balcony have been widely used in high-rise buildings, therefore, a rectangular form of balcony is selected to be modeled on the façade of the 3D model of the high-rise office building with the balcony.

As mentioned earlier (in Section 1.1), there are various definitions to high-rise building, therefore, the researcher stick with the definition as defined by The Federal Emergency Management city of Chicago, because of the classification of high-rise building into different heights which are; 80ft (24m), 275ft (84m), 540ft (165m) and 780ft (288m). Based on the design of the case model building with the floor to floor height of 4m (as specified in the building specification), the total height of the case model building is at 164m height, therefore, the height falls within the

range of 540ft (165m) as defined by The Federal Emergency Management city of Chicago.

The floor level of the 3D model was classified into three parts according to the existing building specification of the case model high-rise office building, which are; the lower-rise (1-15 floor), medium-rise (16-25 floor) and high-rise (25-40 floor). Therefore, based on the theory (as illustrated in Section 2.12) and classification of the floors levels of the case model building, 1st floor, 15th floor, 25th floor and the 40th floor level were used for the investigation of the thermal performance within the office spaces. All the specifications of the case model high-rise office buildings (Cap Square tower) were taken into consideration in configuring the 3D model. During the thermal calculation, the surrounding high-rise buildings were taken into consideration as well as the wind direction and the sun path directions (the weather of Kuala Lumpur, Malaysia). The thermal analysis were observed for four days in a year (22nd of March, 22nd of June, 22nd of September, and 22nd of December) within the office hours (from 9am to 6pm). The 4 cardinal orientation, which are; east, west, north and south orientation were used for the investigation of the thermal performances within the office spaces in the high-rise office building with and without the balcony.

Due to the fact that the case model building is a sealed building (as illustrated Section 5.1.4 in the building specification, Appendix B) and depend totally on mechanical mode of ventilation, the interior spaces of the 3D model of the high-rise office building with and without the balcony were also sealed without the use of any mode of ventilation system or mechanism in order to investigate about the thermal performance (indoor air temperature) in the office spaces. Furthermore, the internal design condition, occupancy rate, operational schedule, internal gains and infiltration rate were kept constant throughout the thermal analysis calculations (all value inputted as the constant variable were obtained from the building specification in Appendix B).

The investigation of this research are totally based on the use of computer simulation software called Ecotect Analysis (2011), therefore the use of any manual device or manual experiment was not involved in the research as all the readings and the results obtained are from a computer simulation energy software.

1.6 Expected Contribution

As mentioned by Mohamed, Prasad and Tahir (2008), in the architectural perspective, the use of balcony in buildings contributes to the shape and articulation of the building, therefore, with the consideration of different design approaches, balconies could contribute to the functionality of a building as a great architectural element. Different research studies such as Mohsen and Oldham (1977); May (1979); and Li et al. (2003) had revealed how the presence of balcony have reduced noise from road traffic with the use of an acoustic material for the configuration of the balcony. Another research study by Chan and Chow (2010) revealed how the presence of balcony in a building can substantially reduce energy consumption due to the shading effect. Suzuki et al. (2001) also revealed how the presence of balcony on the façade of high-rise building (residential and commercial) can prevent the wide spread of fire in the building. Therefore, this present study investigates on how the presence of balcony on high-rise office building in the tropic affects the thermal performance (indoor air temperature) within the office spaces.

1.7 Significance of Research

The significance of the research focuses on the importance of a sustainable element (such as balcony) on high-rise office building. The benefit of dealing with sustainability is distributed in term of environmental, economic, health and safety and community benefit (United-States Green Building Council, 2005). Therefore, this research will enlighten or educate the designers, builders as well as the building occupants or users on the importance of balcony on high-rise office building. As shown in Figure 1.3, the presence of balcony on high-rise office building will improve thermal performance by preventing heat gain and maximize heat loss in the interior spaces of the office building. In terms of safety, the presence of balcony on high-rise office building façade will prevent the wide spread of fire to the upper floors of the high-rise office building in case of a fire outbreak in the interior spaces. Furthermore, this study will educate the designer, builder and the users of the building on how the use of balcony on high-rise office building can reduce energy conservation by reducing the amount of cooling load used in the high-rise office building.

1.8 Chapter Outlines

Chapter 1: Introduction

The Chapter consists of the background of problem, problem statements, research objectives, research questions, scope and limitations of the research, expected contributions, significance of the research and Chapters outlines.

Chapter 2: Literature Review

This Chapter reviews the theory of the climate in Malaysia, and the climate of the study area, which is Kuala Lumpur, solar radiation in Malaysia, air temperature, sky condition in Malaysia and solar geometry. The Chapter further reviews the forms or shapes and features that are present in the high-rise building design and built in a tropical climate like Malaysia. This Chapter also discusses about the review of previous researches done on thermal performance of buildings in the tropical climate, therefore, the gaps of the research was properly defined based on the previous research review.

Chapter 3: Research Methodology

This Chapter discusses the methodology used for evaluating the indoor air temperature in the office space of the high-rise office building with and without a balcony. This Chapter justifies the development of basic model of the office building as well as the experimental procedures, experimental requirements, limitations and the overall stage by stage procedure of the experimental methods.

Chapter 4: Result and Analysis

This Chapter discusses the analysis derived from the simulation. The analysis gives the result of the simulation, which is based on the research questions. The analysis that will be observe during the simulation process are listed below:

- a. The impact of the variation of balcony on the indoor air temperature of the high-rise office building at the north, south, west and east orientation.
- b. The result of the variation of balcony at different height (floor levels) of the high-rise office building with the balcony.
- c. The comparison between the indoor air temperature at the north, south, west and east orientation of the high-rise office building (with and without the balcony), at the investigated floor levels.

Chapter 5: Conclusion and Recommendation

This Chapter discusses the conclusions, which are derived from the results. In this Chapter, recommendations are given on the suitable variations of balcony and the best orientation which balcony should be located on the forms or façade of high-rise office building. Furthermore, future researches related to the area of study are recommended.
