

PHOTOCATALYTIC REDUCTION OF CARBON DIOXIDE AND METHANE TO  
LIGHT HYDROCARBONS OVER NITROGEN DOPED TITANIUM DIOXIDE

MOHAMMADREZA DASTAN

A dissertation submitted in partial fulfilment of the  
requirements for the award of the degree of  
Master of (Chemical Engineering)

Faculty of Chemical Engineering  
Universiti Teknologi Malaysia

AUGUST 2014

To my beloved father, mother and sister

## ACKNOWLEDGEMENT

I would like to express my deepest gratitude to Allah Almighty as with the blessing this project has successfully been concluded.

Foremost, I would like to express my sincere gratitude to my supervisor Professor Dr Nor Aishah Saidina Amin for the continuous support of my research, for her patience, motivation, enthusiasm, and immense knowledge. Her guidance helped me in all the time of research and writing of this dissertation. I could not have imagined having a better supervisor and mentor for my master study. I would like to thank Dr Muhammad Tahir for introducing me to the topic as well for the support on the way. Aside, I would like to express my warmest thanks to Chemical Reaction Engineering Group (CREG) members, and other UTM friends for their support and valuable inputs regarding the research.

Words cannot express how grateful I am to my mother, my father and sister for all of the sacrifices that you've made on my behalf. Your prayer for me was what sustained me thus far. I would also like to thank to all my family members, especially my dear uncle, Mohsen Dastan for supported me in this long journey.

I also wish to express my gratitude to my beloved partner who will always be in my heart for being with me through thick and thin.

## ABSTRACT

Concerns of fossil fuel reserves depletion and environmental pollution problems have led to increased demand for alternative fuels. Therefore, methods for converting natural gas into useful fuels were considered. The main objective of this study is to develop pathways for photolysis reduction of carbon dioxide and methane. Initially nanocatalyst were investigated using cell type photoreactor with  $C_2H_6$  and  $C_3H_8$  as main products during  $CO_2$  reduction with  $CH_4$  over nitrogen (N) / $TiO_2$  nanocatalyst. The yield of  $C_2H_6$  over  $TiO_2$  was  $35 \mu\text{mole g}^{-1} \text{catal}^{-1}$  enhanced to  $166 \mu\text{mole g}^{-1} \text{catal}^{-1}$  using 15% N doped  $TiO_2$ . Besides, the effects of parameters such as,  $CH_4/CO_2$  feed ratio, reaction temperature and light irradiation time on yield of reduction of  $CO_2$  was studied. Finally, the central composite design (CCD) was employed to find individual and interactive effects of the mentioned parameter on yields of  $C_2H_6$  was studied. The predicted values of the yield of  $C_2H_6$  were found to be in good agreement with experimental values ( $R^2= 0.97$ ), which indicate the suitability of the CCD model.

## ABSTRAK

Kebimbangan terhadap pengurangan rizab bahan api fosil dan masalah pencemaran alam sekitar telah membawa kepada peningkatan permintaan bagi bahan api alternatif. Oleh itu, kaedah menukarkan gas asli kepada bahan api berguna dipilih. Objektif utama kajian ini adalah untuk membangunkan laluan bagi pengurangan photolysis terhadap karbon dioksida dan metana. Pada permulaan, naocatalyst dikaji dengan menggunakan sel photoreactor dengan  $C_2H_6$  dan  $C_3H_8$  sebagai produk utama bagi pengurangan  $CO_2$  bersama dengan  $CH_4$  terhadap nanocatalyst nitrogen (N)/ $TiO_2$ . Kadar hasil bagi  $C_2H_6$  terhadap  $TiO_2$  adalah  $35 \mu\text{mole g}^{-1} \text{catal}^{-1}$ , dipertingkatkan kepada  $166 \text{ catal}^{-1} \text{ g} \mu\text{mole}^{-1}$  menggunakan 15% N disaluti oleh  $TiO_2$ . Selain itu, kesan parameter seperti, nisbah suapan  $CH_4/CO_2$ , suhu tindak balas dan sinaran cahaya masa bagi hasil pengurangan  $CO_2$  telah dikaji. Akhirnya, pusat rekabentuk komposit (CCD) digunakan untuk mencari kesan parameter yang dirujuk di atas secara individu dan interaktif bagi penghasilan  $C_2H_6$  telah dikaji. Nilai ramalan bagi penghasilan  $C_2H_6$  menunjukkan keputusan yang baik dengan nilai eksperimen ( $R^2 = 0.97$ ), sekaligus menunjukkan kesesuaian penggunaan CCD model.

## CHAPTER 1

### INTRODUCTION

#### 1.1 Background of Research

Currently, much of the energy used is produced by fossil fuels. Unfortunately, deposits of fossil fuels reducing too fast owing to industrial developments and other energy requirement. The use of fossil fuels increases air pollution problem, as well as the effect of climate change and global warming. To prevent environmental catastrophe and depleting of the fossil fuel resources a generating notice has developed to replace non-fossil and environmentally friendly energy sources.

Methane is introduced as a greenhouse gas. In the form of natural gas, capacious volumes of methane are extensively accessible in nature. The great supply of this gas cusses it attractive raw substance for fuels and chemical synthesis. Based on the newest reports presently, proven world natural gas supplies are approximate to 6609 trillion cubic feet or about 187 trillion cubic (Figure 1.1) [1]. Because of a large quantity of natural gas are predominantly found in far-off areas (Table 1), Therefore gas exploitation and transportation is so expensive. This problem raises the demand for converting gas into liquids on-site [2-6]. Pipeline and tanker can be transported natural gas liquefied by refrigeration. Though, compressed gas to 80 atm is necessary for transfer gas via these pipelines also for distant market it is possible sometimes pipeline not be accessed [2, 4].

**Figure 1.1** World proven reserves of natural gas ( $10^{12}$  m<sup>3</sup>) [1]

Arctic and Siberia	0.1	7.5	42
Other difficult onshore		0.5	2
world	17.5	40.0	129
share of difficult zones (%)	10	31	53

The most common method for converting methane into higher oxygenates and hydrocarbons are not economical because these methods need to specific conditions like high pressure, temperature and particular catalyst. Thus Scientists encourage finding another method for conversion of carbon dioxide and methane to valuable compounds. Methanol is a favorable compound between the products of methane oxidation because it saves so much of energy of methane. In addition, carry out transportation and storage needs. Methanol can be transformed into useful product and oxygenated fuels or may be used straightly as fuel in industry [7].

Heterogeneous photocatalysis is a developing technology also significant for organic synthesis moreover for water and air cleaning. Scientists have worked in this field for years. Heterogeneous photocatalysis has developed as a specific technique for many usages, with the synthesis processing and characterization of new wide band gap and narrow band gap semiconductor materials. In photocatalysis the selectivity of light source is a very significant [7]. The main goal of this study is the reduction of  $\text{CO}_2$  and  $\text{CH}_4$  to higher hydrocarbon with mild condition using semiconductor photocatalyst and light.

## 1.2 Problem Statement of Research

Concerns of fossil fuel reserves depletion and environmental pollution problems have led to increased demand for alternative fuels. Therefore, methods for converting natural gas into useful fuels were considered. One of these methods which is our interest is the photocatalyst reduction of carbon dioxide and methane to hydrocarbons. However, breaking stable  $\text{CO}_2$  molecule through thermal reforming requires higher energy. The basic problem in front in this study are explained as below:

- i.  $\text{CO}_2$  reduction with  $\text{CH}_4$  to hydrocarbon fuels is a two-step process which demanded higher energy. However, on industrial, input energy provided by composition of  $\text{CH}_4$  causes more greenhouse gases effect, it is also uneconomical as well as unfriendly process to the environment.
- ii.  $\text{CO}_2$  photocatalysts reduction to fuels have many advantages, yet photocatalysts and reactors under investigations have lower efficiency due to incompetent yield and repartition of light irradiation over the catalyst surface.
- iii.  $\text{TiO}_2$  semiconductor is widely studied due to great availability, cheap and many other benefits. It's also has lower light adsorption performance, obvious photoactivity and selectivity for photocatalytic  $\text{CO}_2$  reduction to fuels

### 1.3 Objectives of Research

The following are the objectives of this research:

- i. To prepare, characterize and test the nitrogen modified TiO<sub>2</sub> nanocatalysts (N-TiO<sub>2</sub>) for CO<sub>2</sub> reduction to fuels.
- ii. To investigate the effectiveness of various operating parameters on the photoactivity of nanocatalysts in terms of yield
- iii. To study central composite design matrix and response surface methodology to design the experiments and evaluate the interactive effects of the three most important operating variables.

### 1.4 Scope of Research

The following are the scope of this research:

- i. TiO<sub>2</sub> nanoparticle, N/TiO<sub>2</sub> nanoparticle are prepared using sol-gel single step method to study the path of CO<sub>2</sub> photoreduction to hydrocarbon fuels. Nanocatalysts were characterized using X-ray Diffraction (XRD), Field Emission Scanning Electron Microscopy (FESEM), High Resolution Electron Microscopy (HRTEM), Fourier Transfer infrared spectroscopy (FTIR), Brunauer-Emmerr-Teller (BET) Surface Area and UV-Visible Spectrophotometer
- ii. Operating parameter such as light intensity, N loading, reaction temperature, feed ratio and irradiation time were investigated in cell photoreactor.
- iii. Design expert software was used to study the response surface methodology (RSM) and the effect of three most elements on yield of hydrocarbon and find optimum condition for CO<sub>2</sub> and CH<sub>4</sub> photoreduction.

## 1.5 Research Hypothesis

Developing photocatalytic system for efficiently converting CO<sub>2</sub> molecule to hydrocarbon fuels is the main focus of this study. Nanosized catalysts and good designed photoreactor could help to achieve this aim. Hence, most hypotheses of the research described as follows:

- i. The single step CO<sub>2</sub> reduction to hydrocarbon fuels is possible through photochemical process. Nanostructured semiconductor catalyst is organized to be designed in such a way which could enable to overcome obstacles by providing higher light absorption capacity, controlling of surface reaction for increasing selectivity and steps ahead toward higher CO<sub>2</sub> reduction. For this aim TiO<sub>2</sub> nanoparticles doped with structured material.
- ii. Improved photocativity of CO<sub>2</sub> reduction to hydrocarbon fuels will be possible by modified Nonmetal ions to titanium structure. Nitrogen was used because of their determine features and selective production of hydrocarbon fuels.
