NICKEL REMOVAL FROM ELECTROLESS WASTEWATER BY USING
COAGULATION FLOCCULATION AND ION EXCHANGE

NOR AZIMAH BINTI AHMAD

A thesis submitted in fulfilment of the
requirements for the award of the degree of
Master of Engineering (Environmental)

Faculty of Chemical Engineering
Universiti Teknologi Malaysia

AUGUST 2013

Dedicated to my husband, daughter, siblings, nieces, mother in-law and beloved parents for their support, spirit, prayer and throughout any time of need.

ACKNOWLEDGEMENT

In the name of Allah the Most Beneficent and the Most Merciful, alhamdulillah and praise be to Allah the Almighty that I am able to complete my studies here in UTM.

Working on this thesis is a challenging task. Therefore I would like to express my utmost appreciation to my supervisors, Associate Prof. Dr Ariffin b. Abu Hassan and Dr Zainura for their endless guidance, inspiration, encouragement and mentorship to complete this thesis. Also, many thanks to my supportive superior En Raja Ahmad Tajuddin bin Dato Ridzuan. I thank you for your support and understanding.

Last but not least, I would like to thank my family and friends who have directly or indirectly given me support during the completion of this thesis.

ABSTRACT

A massive growth in the industry of electroplating is associated with an increase in the quantity of nickel found in surface water and groundwater. This study focused on the removal of nickel concentration from organic solid waste stream of electroplating industry by using coagulation flocculation and ion exchange methods. In this study, various types of coagulants such as chitosan, WPC 6001, ferric chloride and polyacrylamide were tested to determine the best coagulant for removal of nickel, total suspended solid, chemical oxygen demand and turbidity. The effects of process variables such as pH and coagulant dosage on the performance of these coagulants were also investigated. Polyacrylamide (PAA) was found to be the best coagulant with percentage of 96.6%, 47.2%, 99.6% and 99.6% for removals of nickel, chemical oxygen demand, total suspended solid and turbidity respectively at the pH value of 10 and 1.6 mL/L dosage. From Response Surface Methodology (RSM), the optimal conditions for removal of nickel were found to be at pH 10.46 and 1.64 ml/L PAA dosage. Chelating resin was found to be the best resin with 99.6% nickel removal at pH value of 4. The treated wastewater's nickel content meets Standard A of the Malaysian Environmental Standard.

ABSTRAK

Pertumbuhan pesat dalam industri penyaduran dikaitkan dengan peningkatan dalam kuantiti nikel yang terdapat di permukaan dan air bawah tanah. Kajian ini memberi tumpuan kepada penyingkiran kepekatan nikel dari aliran sisa pepejal organik industri penyaduran dengan menggunakan kaedah pengentalan pengelompokan dan pertukaran ion. Dalam kajian ini, pelbagai ejen pengental seperti kitosan, WPC 6001, ferrik klorida dan poliakrilamida telah diuji untuk menentukan ejen pengental yang terbaik untuk penyingkiran nikel, permintaan oksigen kimia (COD), pepejal terampai dan kekeruhan. Kesan pembolehubah seperti pH dan dos pengental terhadap keberkesanan ejen pengental juga dikaji. Poliakrilamida (PAM) didapati merupakan ejen pengental yang terbaik dengan peratus penyingkiran 96.6%, 47.2% , 99.6% dan 99.6% bagi nikel, permintaan oksigen kimia, pepejal terampai dan kekeruhan pada nilai pH 10 dan 1.6 mL/L dos pengental. Dari *Response Surface Methodology* (RSM), keadaan optimum bagi penyingkiran nikel didapati pada pH 10.46 dan 1.64 mL/L dos pengental poliakrilamida. Resin pengkelatan merupakan resin yang terbaik dengan peratusan penyingkiran nikel 99.6% pada nilai pH 4. Air sisa yang dirawat kandungan nikelnya memenuhi piawaian A menurut Sistem Piawaian Alam Sekitar Malaysia.

CHAPTER 1

INTRODUCTION

1.1 Research Background

The global latent demand for nickel, nickel-alloy wire, insulated wire and cable is estimated to be \$0.6 billion in 2006. The distribution of world latent demand (potential industry earning) is not even across regions. The largest market is Asia, with \$0.2 billion (31.86 percent), followed by North America and the Caribbean with \$0.2 billion (25.67 percent) and Europe with \$0.2 billion (25.16 percent) of the world market (Philip, 2005).

Ruelle (2010) reported that the mining firm Nickel Asia Corporation projected that nickel price will increase from the current \$10.75-\$10.85 to \$11.90 per pound by the year 2012. Nickel is mainly used to produce rust-resistant stainless steel. Also, the demand of stainless steel rose to 9.1 million tons per year in the year 2012; hence the demand of raw nickel is growing by 8.5% annually in the same period. This figure can stipulate the quantities of nickel discharge to the aquatic environment. Thus, nickel contributes to the major surface water and groundwater contaminants.

Nickel pollution is invariably hazardous as the effluent contaminates the air, water and soil. Nickel pollution has deleterious effects on human health. According to the Environmental Quality (Industrial Effluent) Regulation of 2009, the effluent discharge under Standard A specification shall not exceed 0.2 mg/L (EQA, 2009). As a result, decreasing nickel concentration is necessary to reach permissible limits before it is discharged to the environment and to ensure that the effluent is within permissible levels.

The most commonly used methods of chemical treatment are precipitation and coagulation flocculation. The precipitation method can reduce soluble metal ions from a solution by producing metal hydroxides. The process is controlled by a simple pH adjustment. The pH is raised using an alkaline substance such as sodium hydroxide or lime. Then, the solution is converted into an insoluble form and it precipitates. Metcalf and Eddy (2003) reported that the general precipitation methods use hydroxides (OH⁻) and sulfides (S²⁻).

Beside chemical precipitation, Zhen Liang *et al.* (2009) reported that coagulation and flocculation are important processes in waste and wastewater treatment. Most commonly used as coagulant are aluminum based salts and iron based salts. Whereby in the removal of dissolved organic carbons, iron salts have been reported to be more effective than alum salts. This is followed by the flocculation process, where ferric chloride is added to wastewater which causes the colloidal material to destabilize and small particles to agglomerate by forming a large flock to settle (Amudaa and Amoob, 2007).

One well-known chemical coagulation and flocculation method uses chitosan. Chitosan is a biodegradable polymer, which is a non-toxic linear cationic polymer of high molecular weight and is more environment-friendly (Tan *et al.*, 2007). Chitin, a cellulose material similar to biopolymer, is widely distributed in nature, found mainly in marine invertebrates, fungi, insects and yeasts. Chitosan is a good choice

as a coagulant because it is readily soluble in acid solutions (Mohd Ariffin *et al.*, 2008). Pan *et al.* (1999) reported that in various food wastes processing, chitosan is an effective coagulating agent for suspended solids. The high molecular weight (MW) of chitosan enhances the generation of bridging mechanisms (Roussy *et al.*, 2005).

There is a growing interest in the development of natural low-cost materials as an alternative to synthetic polyelectrolytes (Vijayaraghavan and Yun, 2008, Sharma *et al.*, 2006, Crini 2005). Numerous studies have proposed a biological product as an effective coagulation and flocculation agent (Maximova and Dahl, 2006, Deng *et al.*, 2005). Wang *et al.* (2007) reported types of bioflocculants to include biopolymers such as starches, chitosan, alginates and microbial materials produced by microorganisms including bacteria, fungi and yeast. Bioflocculants are safe and biodegradable polymers and generate no secondary pollution; they are applicable in food, fermentation, and water and wastewater treatment. Due to public concerns of polyelectrolyte toxicity, it is believed that bioflocculants will be used more extensively (Bratby, 2007, Sharma and Dhuldhova, 2006, Crini, 2005).

1.2 Problem Statement

There is a steady increase in nickel-laden wastewater generated worldwide as a result of rapid industrialization. In the year 2000, 158,000 tons of nickel was used in the US, 13 % of which was consumed by the galvanic industry (Spoor, 2002). The annual growth of stainless steel demand has been estimated to increase by 9.1 million tons from the year 2009 to 2012. The result shows a growing demand for raw nickel to a tone of 8.5% annually for the same period (Ruelle, 2010). The contaminations that release into the water bodies can cause potential hazardous to aquatic, human health as well as the environment. Nickel has been identified to cause serious

problems in humans such as allergy, dermatitis, sensitization and lung-nervous system damage; in fact, it has been placed on a list of thirteen hazardous metals by the US Environmental Protection Agency (Malkoc, 2006). Thus, it must be treated appropriately before being released into the environment.

At Seagate International (J) Sdn. Bhd, one of the heavy metals that are found to contaminate the wastewater is nickel. The current coagulation flocculation method is uneconomic, due to the in efficient removal of nickel despite using a high dosage of coagulants. The in efficient nickel removal from coagulation flocculation necessitates a subsequent treatment called ion exchange, and constant regeneration is needed. The level of nickel from exhausted ion exchange exceeds Malaysia's industrial effluent specification limit of Standard A (≤ 0.2 mg/L). This scenario may create an excursion condition to Seagate International (J) Sdn. Bhd. Therefore, the wastewater must be treated appropriately before it is discharged into municipal drains. The mean reading for nickel found in the wastewater are shown in Table 1.1.

Table 1.1 : Nickel content at subsequent sampling points

Parameter	OS Influence (mg/L)	OS Effluent (mg/L)	Final Discharge (mg/L)	Standard A Specification (mg/L)
Nickel	94.3	6.94	0.12 – 0.29	0.2

Note:

OS – Organic Solid

Chemical precipitation by coagulation and flocculation is an important process in waste and wastewater treatment. It is used to remove heavy metals such as nickel, suspended solids (SS), reduce chemical oxygen demand COD and turbidity (Amudaa and Amoob, 2007). Common coagulants include aluminum-based and iron-based salts. Other coagulants include commercial organic coagulants, polyacrylamide and chitosan, which is a biodegradable, non-toxic linear cationic

polymer with a high molecular weight (Assaad *et al.*, 2007; Ashoka *et al.*, 2007; Mohd Ariffin *et al.*, 2008). At neutral to alkaline pH, ferric salts will precipitate as an amorphous hydrated oxide or oxy-hydroxide, which has relatively stable and reproducible surface properties. The ability of the ferric hydroxide precipitate to absorb ions of heavy metals is characterized in single- and multi-adsorbate systems. Heavy metals could be absorbed as cations (Cr^{+3} , Pb^+ , Cu^{+2} , Zn^{+2} , Ni^{+2} , Cd^{+2}) in a neutral to high pH environment, and are absorbed as anions (SeO_2^{-2} , CrO_4^{-2} , $\text{VO}_3(\text{OH})^{-2}$, AsO_4^{-3}) in a neutral to mildly acidic pH environment (Patoczka *et al.*, 1998). Studies agree that ferric chloride is more effective than alum for capturing metals from wastewater. It is reported that the efficiency of ferric chloride outperformed alum in arsenic removal, with 96% of arsenic removed using ferric chloride compared to 81% when using alum salts (Johnson *et al.*, 2008).

Studies have also shown that the effectiveness of coagulants is affected by dosage, pH and temperature. These factors need to be tweaked to obtain a high efficiency of treatment. The conventional method to seek optimal conditions is by trial and error approach, using jar tests. This involves changing the levels of one factor and at the same time, keeping the others constant, then running the experiment, observing the results and moving on to the next factor (Mohd Ariffin *et al.*, 2008). This is indeed time and energy consuming. It is also usually incapable of revealing the optimal combination of factors, because it ignores the interaction among them (El Karamany, 2010; Trinh and Kang, 2011; Zheng *et al.*, 2012). Moreover, a majority of wastewater treatment processes contain multiple variables and optimization through the classical method is inflexible, unreliable and time-consuming (Bashir *et al.*, 2012). A better alternative is the use of Response Surface Methodology (RSM) because it includes the influences of individual factors as well as the influences of their interaction. RSM is a technique for designing experiments and building models which evaluate the effects of several factors to achieve optimum conditions for desirable responses with a limited number of planned experiments (Cristian *et al.*, 2010; Raissi *et al.*, 2009; Zheng *et al.*, 2012). There are published RSM studies that focus on the usability of RSM for optimization of various types of wastewater treatment processes (Bashir *et al.*, 2012; Trinh and Kang, 2011; Zheng *et al.*, 2012).

However, it is observed that works concerning the optimization of nickel removal using chitosan are not readily available.

1.3 Research Objective

The main objectives of this research are outlined below.

- To determine the performance of coagulants (chitosan, WPC6001, ferric chloride and polyacrylamide) in the removal of nickel from wastewater.
- To determine the effects of coagulant dosage and pH on the performance of these coagulants.
- To optimize performance of the best coagulant by using RSM.
- To determine the performance of ion exchange (strong acid cation and chelating resin) on the nickel removal process.

1.4 Research Scope

The scope of this research includes:

- The study is carried out in a lab-scale operation which utilized the actual electroless wastewater by analyse the characterization as the influent.

- Study the nickel, COD, TSS and turbidity removal efficiency of the various coagulants (chitosan, WPC6001, ferric chloride and polyacrylamide (PAA)) at different pH levels(4 – 11) and coagulant dosages.
- Evaluating the optimum pH and coagulant dosage for PAA using response surface methodology (RSM).
- Study the performance of different ion exchange (strong acid cation and chelating resin) on nickel removal at pH 4.
- Evaluate the operation condition for chelating resin at different pH and contact time.

1.5 Significance of The Study

Large quantities of trace metals such as nickel are discharged from various industrial processes into the environment; endanger humans as well as flora and fauna. Growing public concern about environmental protection/sustainability and public health has led to the enactment of environmental laws and environmental standards being set up. Therefore, to meet these standards, there is an urgent need for manufacturers to minimize release of these metallic pollutants into bodies of water by treating the wastewater prior to discharging it into the environment.

This has prompted more researches to be conducted to find more efficient ways to remove these nickels from the wastewater before being released into the environment. Therefore, the result from this research will serve as a guide to treat wastewater for electroless industries, regulatory bodies and policymakers.

1.6 Organization of the Thesis

This thesis consists of five chapters. Each chapter gives information about a specific research area.

- **Chapter 1** details the research background, research aim and objectives as well as the scope of the study.
- **Chapter 2** reviews literature on general information on nickel, electroless plating industry wastewater, coagulation-flocculation method and ion exchange.
- **Chapter 3** covers a general description of the experimental setup and the procedures in carrying out the research work. It includes: sample collection and characterization, assessment of nickel removal efficiency by different coagulants, assessment of nickel removal efficiency by different ion exchange resins and determination of optimum operating conditions for chemical precipitation using response surface methodology (RSM).
- **Chapter 4** presents and discusses the results of the research. It includes the effect of pH and coagulant dosage on the efficiency of nickel removal. The performances of various ion exchange resins are discussed. Finally, the results of the optimization process using RSM is presented.
- **Chapter 5** deals with conclusions and recommendations. It presents the conclusions derived from this research study and recommendations for future studies.
