

IMAGE FORENSIC FOR DIGITAL IMAGE COPY MOVE FORGERY
DETECTION

YEAP YONG YEW

A project report submitted in partial fulfilment of the
requirements for the award of the degree of
Master of Engineering (Computer and Microelectronic Systems)

Faculty of Electrical Engineering
Universiti Teknologi Malaysia

JANUARY 2018

For my beloved parents, aunt, sister and family members.

ACKNOWLEDGEMENT

Firstly, I would also like to express my deepest gratitude to my supervisor, Dr. Usman Ullah Sheikh for his support and guidance. Dr. Usman has been instrumental in the completion of the research by providing timely advice and feedback that ensured that the research is of high quality. Furthermore, I would like to thank Dr. Usman for his frequent trips to Penang for sync up and research discussion purposes. The research would not have been possible without Dr. Usman's assistance.

I would like to recognize and thank the panel of judges, namely Associate Professor Muhammad Mun'im Ahmad Zabidi and Dr. Ab Al Hadi Ab Rahman for their constructive feedback during the presentation. The feedback is critical as it enhances the research quality.

Lastly, I would like to thank my family members, especially my parents, aunt and sister, who have been nothing but supportive of me. They were understanding and constantly showered me with words of encouragement throughout the research. I would also like to recognize and thank my colleagues who provided work coverage during the research duration and also my fellow course mates who are always there to lend a helping hand.

ABSTRACT

In recent years, digital image forgery detection has become an active research area due to the advancement of photo editing software. In general, image forgery detection can be classified into two types, namely active and passive detection. Active forgery detection relies on embedded authentication code in the image while passive forgery detection relies solely on the images for authentication. The forgery detection techniques are used to identify images tampered with common techniques such as copy move, slicing, contrast alteration and sharpening/blurring. This project focuses on passive forgery detection on images tampered using copy move technique, better known as Copy Move Forgery Detection (CMFD). A CMFD technique consisting of oriented Features from Accelerated Segment Test and rotated Binary Robust Independent Elementary Features (Oriented FAST and rotated BRIEF) as the feature extraction method and 2 Nearest Neighbour (2NN) with Hierarchical Agglomerative Clustering (HAC) as the feature matching method is proposed. The ORB parameters, namely the number of features to retain and patch size are optimized using Particle Swarm Optimization (PSO). The optimization is essential in obtaining a balance between performance and runtime. Evaluation of the proposed CMFD technique is performed on images which underwent various geometrical attacks. With the proposed technique, an overall accuracy rate of 84.33% and 82.79% is obtained for evaluation carried out with images from the MICC-F600 and MICC-F2000 databases. Forgery detection is performed accurately, with True Positive Rate of 91% and above, for tampered images with object translation, different degree of rotation and enlargement. However, the performance degraded for tampered images with reduced copied object size and asymmetrical scaling, with True Positive Rate of 73.68% and 38.15% respectively.

ABSTRAK

Dalam beberapa tahun kebelakangan ini, kemajuan perisian penyuntingan foto telah menjadikan pengesanan pemalsuan imej digital sebagai satu bidang penyelidikan yang aktif. Pengesanan pemalsuan imej boleh diklasifikasikan kepada dua jenis, pengesanan aktif dan pasif. Pengesanan pemalsuan aktif bergantung kepada kod pengesanan yang tertanam dalam imej sementara pengesanan pemalsuan pasif hanya bergantung kepada imej untuk menjalankan pengesanan. Cara-cara pengesanan pemalsuan imej digunakan untuk mengesan pemalsuan imej termasuk salinan langkah, penyalinan dari imej lain, pengubahan kontras dan pengaburan. Projek ini memberi tumpuan kepada pengesanan pemalsuan pasif pada imej yang dicemari menggunakan teknik salinan langkah. Teknik tersebut dikenali sebagai Pengesanan Pemalsuan Salinan Langkah (CMFD). Teknik CMFD yang dicadangkan dalam projek ini terdiri daripada *oriented Features from Accelerated Segment Test* dan *rotated Binary Robust Independent Elementary Features (Oriented FAST dan rotated BRIEF)* sebagai kaedah pengekstrakan ciri dan *2 Nearest Neighbor (2NN)* dengan *Agglomerative Hierarchical Clustering (HAC)* sebagai kaedah pencocokan ciri. Parameter ORB, iaitu bilangan ciri untuk dikekalkan dan saiz patch telah dioptimumkan dengan menggunakan cara Particle Swarm Optimization (PSO). Pengoptimuman adalah penting dalam menyeimbangkan antara prestasi dan tempoh masa yang diperlukan. Penilaian teknik CMFD yang dicadangkan dilakukan pada imej yang mengalami pelbagai serangan geometri. Dengan teknik yang dicadangkan, kadar ketepatan keseluruhan adalah 84.33% dan 82.79% bagi penilaian yang dijalankan dengan imej dari pangkalan data MICC-F600 dan MICC-F2000. Pengesanan pemalsuan imej dilakukan dengan tepat dan kadar positif sebenar sebanyak 91% dan ke atas diperolehi untuk imej dengan terjemahan objek, tahap putaran yang berbeza dan pembesaran. Walau bagaimanapun, prestasi menyusut bagi imej di mana saiz objek yang disalin dikurangkan dan penskalaan tak simetri, dengan kadar positif benar masing-masing sebanyak 73.68% dan 38.15%.

CHAPTER 1

INTRODUCTION

This chapter introduces this research work by providing the project background and potential impact. It focuses on the research motivation and the research gap, before concluding the chapter with the organization of the thesis.

1.1 Problem Background

In this day and age, digital images tampering has been made easy with widely available image editing softwares, such as Adobe Photoshop. The advancement of image editing softwares has reached a level such that image tampering can be done without degrading its quality or leaving obvious traces. This is alarming as images are now being presented as supported evidences and historical records in various fields, such as in forensic investigation, law enforcement, journalistic photography and medical images.

Moreover, in many instances tampered images have appeared in the news or social media, such as the manipulated images of Iranian missile test released on the 9th of July 2008 by Sepah News, the official media arm of Iran's Revolutionary Guard. The tampered image, shown in Figure 1.1 is aimed at exaggerating the country's military capabilities. The tampered image made its way into media circulation, making the front page of notable newspapers, such as The Financial Times and The Los Angeles Times. The forgery is detected a day later when the same source released another image taken from the same angle at almost the same time, but with different content.

The scientific community is also not spared from image tampering. Farid et al. [1] stated that 20% of accepted manuscripts of the Journal of Cell Biology contains inappropriate figure manipulation. Hence, image tampering and detection

have garnered substantial attention as manipulated images can be used to misrepresent their meaning with malicious intent.

Figure 1.1: (a) Original image of Iranian Missile Test (b) Forged image of Iranian Missile Test

Among the image manipulation techniques in the literature, Abd Warif et al. [2] stated that copy-move forgery and copy-move forgery detection (CMFD) is one of the most widely studied field. In general, CMFD involves the manipulation of an image where an object, texture or letter is copied from one region of an image and inserted into another region of the same image.

1.2 Problem Statement

The project focuses on applying widely used keypoint based algorithms in the field of object recognition for CMFD. The proposed CMFD technique, consisting of both feature extraction and feature matching, would serve as an alternative to the current state of the art CMFD method using Speeded Up Robust Features (SURF).

Before SURF was introduced in the field of CMFD, Scale-invariant Feature Transform (SIFT) is widely regarded as one of the best keypoint based algorithm for CMFD. With SURF, the algorithm proposed multiple optimization which successfully reduced the computation time by 3 times. However, the improvement came at the expense of the accuracy rate.

Hence, this work aims to identify a Copy Move Forgery Detection technique, consisting of both feature extraction (descriptor) and feature matching, capable of obtaining better accuracy rate while maintaining the computational time seen with SURF.

1.3 Project Objective

The object of this project is to identify a Copy Move Forgery Detection technique, with both feature extraction and feature matching technique, capable of obtaining better accuracy rate while maintaining the computational time seen with SURF. Also, the proposed CMFD method is compared with existing CMFD techniques in terms of performance.

1.4 Scope of Study

The scope of this project focuses on proposing a CMFD technique, with both descriptor and feature matching methods, and its performance on accurately detecting tampered images. Apart from the proposed CMFD techniques, an existing CMFD technique, namely SURF, which is the state of the art feature extraction method is also reproduced.

The performance of the proposed CMFD technique is evaluated using images which have underwent different geometrical attacks, namely translation, different degrees of rotation, symmetrical and asymmetrical scaling. The proposed CMFD technique is also tested on images with multiple copy-move regions. The proposed work is implemented using MATLAB and tested on the following dataset: MICC-F600 and MICC-F2000.

1.5 Organization

The thesis is organized as follows: Chapter 2 presents the literature review on Copy-Move Forgery Detection, focusing on block based and keypoint based CMFD techniques. Chapter 3 presents the research methodology of the proposed CMFD technique, focusing on SURF and ORB as the feature extraction methods and 2 Nearest Neighbour (2NN) and Hierarchical Agglomerative Clustering (HAC) as the feature matching method. Chapter 4 presents the result of our proposed CMFD technique with a summary of the contribution and achievements of the project. Lastly, we conclude the project by a conclusion and a discussion on potential future works to build on the project.
