HARNESSING ENERGY VIA PIEZOELECTRICITY VIBRATION

TEH SUI LIN

A project report submitted in fulfilment of the
requirements for the awards of the degree of
Master of Engineering (Mechanical)

Faculty of Mechanical Engineering
Universiti Teknologi Malaysia

JUNE 2016

To my beloved family who always gives me strength to complete this thesis, believe in me and guide me all of my pursuits.

ACKNOWLEDGEMENT

This dissertation would not have been possible without the guidance and help of several individuals who, in one way or another, contributed and extended their valuable assistance throughout the duration of this study.

First and foremost, it is with tremendous gratitude that I acknowledge the continual help and support of supervisors, Associate Professor Dr. Intan Zaurah Binti Mat Darus. The patience they have shown during encountered obstacles, along with the inspiration and expertise they provided will not be forgotten. The completion of this work would not have been possible without their recommendations and assurances.

Finally, my numerous friends in the UTM who provided encouragement and frequent relief during my study duration here must be mentioned. There are just too many to name individually here but I thank you all for the happy memories.

ABSTRACT

In an effort to eliminate the replacement of the batteries of electronic devices that real difficult or impractical to service once deployed, harvesting energy from mechanical vibrations or impacts using piezoelectric materials has been researched over the last several decades. However, a majority of these applications have very low input frequencies. This represents a challenge for the researchers to optimize the energy output of piezoelectric energy harvesters, due to the relatively high elastic moduli of piezoelectric materials used to date. This project reviews the current state of research on piezoelectric energy harvesting devices at low frequency (<100 Hz) applications using vibrating motor and the methods that have been develop to improve the power outputs of the piezoelectric energy harvesters. This project study is divided into two main parts which are simulation from the forced vibration data and laboratory experiment on vibrating motor. The simulation results shows that as the acceleration magnitude increases, the average direct voltage also increases from 4.5 mV to 8.1mV and the average power output that could be harnessed also increased from 22.5 μW to 40.5 μW. The experimental work energy harvesting structures focused on a bimorph piezoelectric rectangular plate (two faced PZT layer bonded to a brass substrate) that would be driven by ambient vibration source (motor). Multiple tip mass value on the effect of power generated was investigated in this project. It is shown that motor speed at 100 rpm has the highest power generated both with (1667.21 μW) and without (10.15 μW) the addition of tip mass. Besides, it is also observed as the motor speed increased from 900 rpm to 1000 rpm, lower tip mass value required to optimize the power generated. 20g of tip mass value is required to generate 218.21 μW at motor speed 900 rpm, 10g of tip mass value is required to generate 626.29 μW at motor speed 1200 rpm These power output is sufficient for low powered electronics which can be used in variety of applications as indicated in the literatures reviewed.

ABSTRAK

Dalam usaha untuk menghapuskan penggantian bateri peranti elektronik yang sebenar sukar atau tidak praktikal untuk perkhidmatan sekali digunakan, tenaga penuaian dari getaran mekanikal atau kesan menggunakan bahan-bahan piezoelektrik telah dikaji sejak beberapa dekad yang lalu. Walau bagaimanapun, majoriti aplikasi mempunyai frekuensi input yang sangat rendah. Ini merupakan satu cabaran bagi para penyelidik untuk mengoptimumkan output tenaga penuai tenaga piezoelektrik, kerana modulus elastik yang agak tinggi bahan-bahan piezoelektrik digunakan setakat ini. Projek ini mengkaji keadaan semasa penyelidikan mengenai piezoelektrik peranti penuaian tenaga pada frekuensi rendah (<100 Hz) aplikasi yang menggunakan bergetar motor dan kaedah yang telah membangunkan untuk meningkatkan output kuasa Penuai tenaga piezoelektrik. Kajian projek dibahagikan kepada dua bahagian utama iaitu simulasi daripada data getaran paksa dan eksperimen makmal ke atas bergetar motor. Keputusan simulasi menunjukkan bahawa sebagai magnitud kenaikan pecutan, voltan langsung purata juga meningkat daripada 4.5 mV kepada 8.1mV dan output kuasa purata yang boleh dimanfaatkan juga meningkat daripada 22.5 μW kepada 40.5 μW. Struktur penuaian tenaga kerja eksperimen memberi tumpuan kepada bimorph plat segi empat tepat piezoelektrik (dua dihadapi lapisan PZT terikat kepada substrat tembaga) yang akan dipacu oleh sumber getaran ambien (motor). Pelbagai nilai berat hujung atas kesan kuasa yang dihasilkan telah disiasat dalam projek ini. Ia menunjukkan bahawa kelajuan motor pada 1000 rpm mempunyai kuasa yang paling tinggi yang dihasilkan dengan kedua-dua (1667.21 μW) dan tanpa (10.15 μW) penambahan berat hujung. Selain itu, ia juga diperhatikan sebagai kelajuan motor meningkat daripada 900 rpm kepada 1000 rpm, lebih rendah nilai hujung berat yang diperlukan untuk mengoptimumkan kuasa yang dijana. 20g nilai berat hujung diperlukan untuk menjana 218.21 μW pada kelajuan motor 900 rpm, 10g nilai berat hujung diperlukan untuk menjana 626.29 μW pada kelajuan motor 1200 rpm ini output kuasa yang mencukupi untuk

elektronik berkuasa rendah yang boleh digunakan dalam pelbagai aplikasi seperti yang dinyatakan dalam literatur dikaji semula.

CHAPTER 1

INTRODUCTION

Sensors that can be used in remote or not easily accessible places are becoming an attractive solution in a wide variety of applications such as habitat or structural monitoring.

The limitations in providing power with batteries have led to a growing interest in “energy harvesting”. Energy harvesting is a technology that converts the excess energy available in an environment into usable energy for low power electronics. The term harvest and harness are used concurrently in this thesis.

It shows that for short periods (months to a year) fixed energy content methods such as batteries or fuel cells are sufficient. Fixed energy methods possess a given amount such as quantity of fuel or a battery without any charging equipment. As the desired lifespan increases the constant output energy harvesting methods become interesting. These are systems of which the output is constant amount of power, consider solar cells under constant illumination or windmills under constant wind conditions, vibratory sources are an excellent alternative.

Some battery types and most applicable energy conversion mechanisms are compared with respect to their long term and short term power densities. Power density, meaning the amount of average energy generated per unit time and volume, is the most convenient and widely used criterion in the literature.

According to Table 1.1, batteries are reasonable for one year applications, whereas energy harvesters are required for long lifetime applications.

Table 1.1 : Comparison of energy sources.[1][2]

	Power density ($\mu W/cm^3$)	
	One year lifetime	**Ten year lifetime**

Fuel cells:methanol	280	28

In Figure 1.1, components of a vibration energy harvesting system are depicted. This flow chart can be generalized for all energy harvesting systems in which an energy source, a conversion device, a conditioning circuit and an electric load are the main components of the general energy harvesting system.

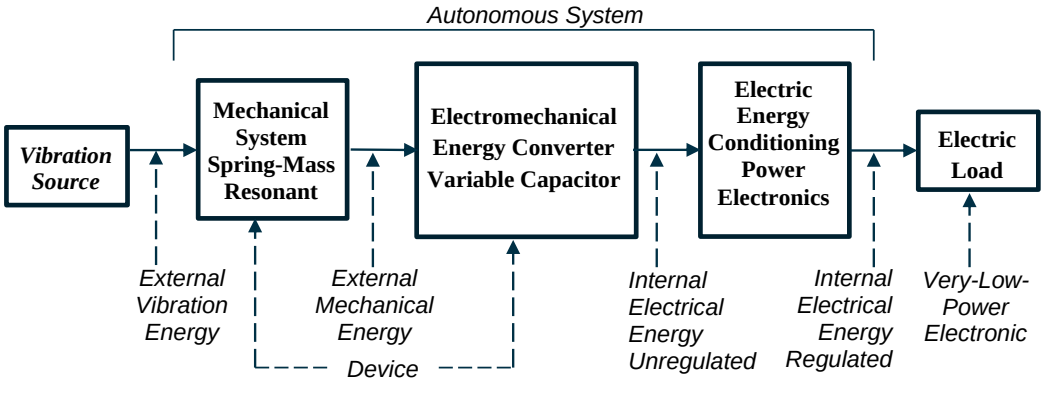

Figure 1.1 : Vibration Energy Harvesting System Components.

The general system basically aims to accomplish five consecutive tasks[1]:

- Collecting the maximum energy from the energy source
- Converting the ambient energy into electric energy efficiently
- Rectifying and storing the maximum amount of electric energy
- Regulating the output voltage level depending on the application
- Transmitting the electric energy to the load when it is required

The contribution of this thesis is mainly based on implementing the active energy harvesting concept. An energy scavenging system can be partitioned in two sections: the energy-scavenger itself and the electronic interface. The first one is the energy transducer while the second one is the electronic circuit which manages the energy. One of the most important objectives of the electronic interface is to realize the required ac-dc conversion. Since the output power level of the energy-scavenger can be very low, the conversion should be as efficient as possible.[3]

The electronic interface can be divided in three subsystems as shown in the fig Figure 1.2 a) the ac-dc converter, b) the energy storage and c) the adapter. The last one supplies a regulated voltage to the load even when it sinks a time dependent energy during its work cycle. Furthermore, to obtain the maximum transfer of the energy from the energy scavenging system into the load, an optimum value of the output impedance exists [3].

Besides the working principle, the main difference between the various transducers is the scavenged power per cubic centimeter. In Table 1.1, the power density of the three transducers are shown: it is clear that the piezoelectric one is the most efficient. Furthermore its power density is compatible with the power consumption of modern wireless sensor nodes [3].

Table 1.2 : Power density, reported in literature, of three energy transducers used to convert the energy of the mechanical vibrations.

Working Principle of the Energy-Scavenger	**Power-Density [µW/cm^3]**

Electrostatic	50
Piezoelectric	250

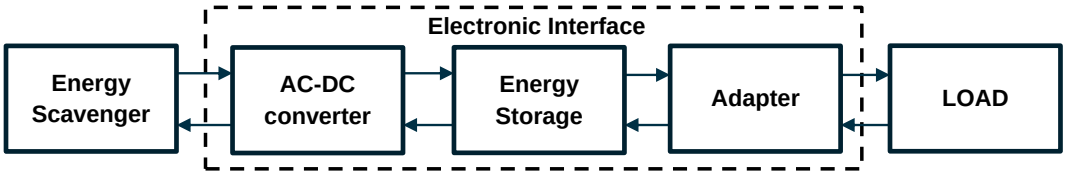

Figure 1.2 : General block diagram of an energy scavenging system.[3]

1.1 Motivation and contribution of the thesis

Power harvesting is a practice that has been widely used in developing devices that are self-powered and refers to the technique of acquiring energy from the environment and convert it into useful energy.

Due to increased demand relative to the mobility of electronic devices, the field of research in regarding alternative ways of low power energy generation has increased in recent years. Moreover, the evolution of battery technology remained practically stagnant over the past decade in relation to computer system.

In the past decades, several systems have been developed using smart materials. Typically, piezoelectric materials are used commercially as motion sensors or amounting to force. The piezoelectric crystals are transducer elements for accelerometers, actuators, dynamic pressure sensors and load cells. Power supply is a limiting factor in wearable devices since the employment of a primary battery (a battery to be used only once) means that the user of the portable product has to carry an extra battery while the use of secondary battery (rechargeable battery) means that the user has to plug in the portable product to grid to recharge it. This fact limits the mobility of the wearable device which is restricted to the lifetime of the battery. Furthermore, due to the costs and inaccessible locations, the replacement or recharging of batteries is often not feasible for wearable devices integrated in smart clothes. Moreover, the increasing number of battery-powered portable products is creating an important environmental impact.

Nowadays, wireless sensor networks are drawing much attention in monitoring and controlling plants, resources and infrastructures. A critical component of the wireless sensor network is the power supply. If power is supplied through cables, the wireless network will not be truly wireless. Therefore, traditional batteries are usually used in wireless sensor networks. But in many applications, replacing batteries, due to their limited lifetime, is very inconvenient. The labor and cost associated with changing hundreds or thousands of batteries would be troublesome and expensive in maintaining the network.

Through piezoelectric energy harvesting has been thoroughly investigated since the late 1990s, it still remains an emerging technology and critical area of interest. Energy harvesting application fields so far mainly focused on low power devices due to their limited transduction efficiencies. To date, researchers are following distinct ways in developing piezoelectric energy harvesting technology. New materials, configuration approaches and operating modes are under study, and some of these valuable solutions were proposed in order to achieve large bandwidth harvesters that are able to scavenge energy from diverse environments [4].

1.2 Objective

The objective of this project is to design, simulate and develop an instrumentation to harness energy from micro vibration using smart materials.

1.3 Scopes

Aiming at a vibration based piezoelectric energy harvester, the research can be divided into 2 phases, that is, harvester and its host structure.

For the host structure, the acceleration magnitude is considered both in the simulation and the experiment work. Different motor speed is used to conduct the experiment work.

For the harvester, the designing in the mechanical system is focused in the experiment. The external mass is added to the harvester tip end is the main concern of this work to optimize the power output.

1.4 Methodology

The methodologies involved in this study are shown in Figure 1.4. The project starts by collecting reading materials specifically on sources of vibration, methods of converting ambient vibration energy into electrical energy, types of piezoelectric material, piezoelectric energy harnessing circuit, strategies used to optimize the power harvested and their applications.

The study on piezoelectric energy harnessing has been divided into two main parts which are (1) simulation of the vibration environment and (2) laboratory experiment on vibrating mechanical equipment. Both simulation and laboratory experiment will undergo the same process such as piezoelectric vibration to

electricity conversion, rectification and energy storage. For the experiment, the power generated with the aid of tip mass was studied.

The vibration data acquired from experimental study by previous researcher in order to determine the possible amount of power density output that can be produced for the specific acceleration input. With the promising amount of power density output produced during simulation, the laboratory experiment on vibrating mechanical equipment will be conducted by vibrating mechanical equipment and identifying electronic devices that can fully utilize this power.
