Abstract

This paper analyzed total direct cost that is paid by the Social Security Organization of Malaysia (SOCSO) to the Malaysian workers due to musculoskeletal disease. The objectives of this study are 1) to determine the total direct costs incurred as a result of cases of chronic musculoskeletal injuries that was approved by SOCSO from 2009 to 2014 and 2) to examine the age category imposed for the total average cost of the highest MSDs claims for the four categories setting. The data provided by SOCSO on occupational diseases and adopt the top-down approach which includes of 416 claims reported between 2009 and 2014. The categories recorded are the highest total direct cost for types of industries, types of injury, causes of accident and type of body parts. The age claimant is then identified from total average cost earned from the highest total direct cost of the four categories. Manufacturing industry, strenuous movement, sprain and strain and back are recorded as highest total direct cost with the cost of RM 5,181,282.34, RM 7,088,839.51, RM 8,753,975.13, and RM 5,526,590.69, respectively. The age group of 35 – 44 years is recorded as the highest total average cost of these four parameters. This study will provide the basis for future studies and intervention on MSD related injuries in working environment in Malaysia.

Keywords: Body part location; Cause of accident; Direct cost; Injury; Musculoskeletal disorders

1. Introduction

Malaysia is one of the growing industrialized countries and expected to have developed country status in the next decade [1]. Industries are booming at a very high rate and therefore the hazard of occupational diseases are always considered as most significant problems for workers in the future, especially for developing countries like Malaysia [2]. Meanwhile for the developed countries such as Canada that already claims occupational diseases are common health problem and is the major contributor to the disability and cost in working for population [3]. Consequently, both developed and developing countries face the same problems and being apprehensive to all organizations nowadays.

A study conducted in the United States mentions that about 29%-35% of occupational diseases and injuries belong to Musculoskeletal Disorder [4]. The others had reported a survey in United Kingdom Health and Safety Executive, which stated that musculoskeletal disorders were the most common disease and 37% of working days lost were from MSD [5]. In Malaysia, a total number of 553 claims were recorded related to MSD between years 2009 until 2014 which corresponds to 25.22% of the overall occupational diseases that lead to temporary and permanent disability [6].

MSD problems are generally caused by the work-related physical risks factors such as repetitiveness, work environment, and psychosocial factors. This MSD will give labors experience of

pain or discomfort in the muscles, nerves and tendons region including other soft tissue [7, 8]. Database records of SOCSO for the period 2009-2014 shows that the most occurrence body parts injury is human's back part which accounts for 50.2% followed by hip 36.5% and shoulder 2.6% [6]. However, the percentage of claimants will be vary depending on the scale of sectors. There is a study that shows MSD commonly occurred at lower back 48%, shoulder 13% ,upper extremities 5% , knee 5%, ankle or foot 2% and multiple sites 5% [9]. The other researcher specified the lumbar spine for most frequent cases of MSD [4, 9].

MSD causes loss of workdays that affect the productivity of business and after that creates negative economy on individual and community [6]. MSDs cases have damaged about the US \$171.7 million of productivity losses in Columbia in 2005 [10]. The productivity can be related to the efficiency between the input and output of the workers but the problem arise when that number of output unit becomes less than input hours due to workers being away from work due to illness and absenteeism [11, 12]. While the study in Korea shows that the economic cost of MSD was estimated to be \$6.89 billion, which represent 0.7% of the Korean gross domestic product in 2008 [13].

The study in the United States differentiates the cost between direct cost and indirect cost [3]. Direct cost is classified as an illness cost being compensated, medical cost, indemnity cost and others related cost during the claimants' recovery. Meanwhile, indirect cost basically refers to the losses of potential output, at work or home this lead to morbidity or premature mortality and reduction

of quality life [14]. In a separate study, the researcher had proposed three cost categories in estimating the cost related to MSDs. The three categories include of direct cost, indirect cost, and quality of life cost [10]. Meanwhile, the other researcher defined the cost into three categories which are a direct cost, indirect cost, and intangible cost [13]. According to Middlesworth indirect cost is difficult to measure as the need to consider the loss of production time, training and compensate a replacement worker and related to absenteeism filing because it is hard to determine precisely how each activity has affected the claiming [15].

Currently, there is little study being done on the cost associated with total direct cost claimed in Malaysia. There are studies being done at oversea on total direct cost which includes medical cost and wage compensation cost do not include the cost of return to work and rehabilitation cost [3, 4, 10]. Whereas, the other researchers only report compensation claims cases from SOCSO database for the period 2002 to 2006 and focusing to the non-governmental employee [1].

This paper is limited to secondary data only and primary data are not included. Only total direct costs (compensation claim, medical cost and return to work and rehabilitation cost) are consider in this study. The purposes of this research are: 1) to determine the total direct costs incurred as a result of cases of chronic musculoskeletal injuries approved by SOCSO from 2010 to 2014 and 2) to examine the age category imposed for the total average cost of the highest MSDs claims for the three category setting which are types of industry, types of injury, causes of injury and body part.

2. Methodology

The descriptive data of occupational diseases claims were provided to the research team by Social Security Organization of Malaysia (SOCSO). The data is limited from the period 2009 until 2014 and adopted top down approach where only MSD cases is filtered in as to align with the scope of study. The chosen MSDs cases are due to highest claims during the five years' period compared to miners' nystagmus, hearing impairment caused by noise, any other physical causes, and agent's diseases caused vibration, and occupational vitiligo. In addition, only permanent disability MSDs cases with paid status were accounted and others type of status (i.e. claim rejected, wrong data entry, incomplete documents and no payment made) were filtered out in order to validate the data.

As to achieve the objective of this study, the cost of medical and return to work and rehabilitation were then collected at each selected branches. The selected branches were chosen by comprising the highest percentage with the others branches that accumulating 77.5% (n=416) from the overall reported by SOCSO (537 cases). The selected branches were Melaka (n=207), Butterworth (n=55), Sungai Petani (n=49), Kuantan (n=49), Kuala Lumpur (30) and Rawang (26). The collection data varied depending on each branch and losing of many data is possible due to lack of record keeping. The data of claimants such as name and identification number are not reporting in this study as to protect the claimants' personal data.

The critical part in collecting the cost data for this study is the financial and distribution of cost due to confidential data. Hence, the authority permission is needed in order to have data from the SOCSO branches. The main idea of visiting the main SOCSO office, located at Jalan Ampang, is to get an overview on how the cost is being distributed to the claimants. Return to work and rehabilitation cost record is only kept by the main SOCSO branches. Meanwhile, the medical cost claims are recorded by every SOCSO branches. The cost claims at each branch are collected through visits, emails and fax.

The process of descriptive data analysis is performed by analyzing the demographic characteristics such as gender, age groups, type of industries, causes of injury, the location of body part injuries and type of injuries. In order to determine the age category, the study in Ohio is referred. The researcher classified the into six

categories which are 16-24 years, 25-34 years, 35-44 years, 45-54 years, 55-64 years and above 65 years [8]. The total direct costs were calculated from the actual payment made by SOCSO to an employee based on permanent disability cases for the year 2009 until 2014.

Statistical Package for the Social Science (SPSS) is a tool used in order to analyze the descriptive data. SPSS is one of the most popular statistical packages that can perform highly complex data manipulation. Those generations need as to manipulate the huge amount of numbers related to distribution cost between variables setting

3. Results and Discussion

3.1. Compensation Cost Claimants on Type of Occupational Disease

Table 1 shows the comparison of compensation cost between MSD and other diseases case reported every year from 2009 until 2014. Table 1 shows the types of the occupational disease being reported by the SOCSO over the year 2009 until 2014. The musculoskeletal disorder has the highest cases claimed among the others diseases 25.5%. The other diseases include of thirty-seven types of disease (miners' nystagmus (21.0%), diseases caused by any other physical agents (16.4%), hearing impairment caused by noise (16.3%), occupational vitiligo (6.0%), diseases caused by vibration (5.8%), diseases caused by chemical agents (1.7%), any other respiratory diseases (1.2%), and the rest of thirty-one other diseases counted less than 1%. From the Table 1, the total cost incurred in the occupational diseases is increasing over the periods. For the year 2009, MSD cost was RM 1,049,700.86. The year 2010, the cost increased to RM 912,485.64 even though the sample size was same as of the year 2009. Meanwhile, for the year 2011 the total cost claim had slightly increased to RM 1,791,629.86 compared to the year 2009. The claimant for the year 2012 increased and the consequent of cost significantly grew to RM 3,274,073.07. The number of claimants is dropping to n=101 that cost RM 2,624,981.55 for the year 2013. For the year 2014, the total cost was costlier compare for the year 2012, RM 3,940,486.61. This lead to the total cost of 537 MSD claims to be RM 13,593,357.59. The occupational has clear increasing trend over the years. The total cost for year 2009 is RM 1,599,074.26, RM 3,722,228.27 for year 2010, RM 4,714,369.26 for year 2011, RM 6,148,457.45 for year 2012, RM 8,163,071.11 for year 2013 and the total cost drastically increased for year 2014 with the sum up claimants n=1567 (RM 34,465,120.24). The accumulated number of occupational diseases made up to n= 2104 claimants with average total cost mean RM 22,841.48.

3.2. Total Direct Cost Claimants on Socio-Demographic

Table 2 shows the total direct average cost claims for socio-demographic characteristic for period 2009 to 2014. Male workers were recorded as higher claimants with average mean cost RM 28,220.00 as compared to female workers with the average cost RM 20,600.00. The age between 35-44 years old significantly shows the highest average total direct cost claims with RM 28,264.42 (38.9%). This category of age also has the highest total direct cost compared to the other category with costing of RM 4,578,835.89 for that particular age. For the second higher claims on average total direct cost was at age 25-34 (RM 28,029.98) and then at age 45-54 (RM 23,934.81) follow to claimants from age 16-24 (RM 18,488.10) and the least average total direct cost was on age 55-64 (RM 15,161.27).

Table 1 Total cost for Occupational Disease (2009 to 2014)

Year	Type of Diseases			
	Musculoskeletal		Other Diseases	
	n	RM	n	RM
2009	40	1,049,700.86	81	1,599,074.26
2010	40	912,485.64	181	3,722,228.27
2011	74	1,791,629.86	222	4,714,369.26
2012	129	3,274,073.07	276	6,148,457.45
2013	101	2,624,981.55	355	8,163,071.11
2014	153	3,940,486.61	452	10,117,919.89
Total	537	13,593,357.59	1567	34,465,120.24

Table 2. Average total direct cost claimants for socio-demographic characteristic

Variable	n	(%)	Total Direct Cost	Average total direct cost
Gender				
Male	322	77.4	9,086,979.96	28,220.00
Female	94	22.6	1,936,435.29	20,600.00
Age Group				
16-24	19	4.6	351,273.94	18,488.10
25-34	138	33.2	3,868,137.92	28,029.98
35-44	162	38.9	4,578,835.89	28,264.42
45-54	86	20.7	2,058,393.53	23,934.81
55-64	11	2.6	166,773.97	15,161.27
Above 65	0	0	0	0

The age category number of average total direct cost follows the bell shape distribution. Even though the other researchers had set different category, but the trend is still following the bell shape [1, 3, 7, 9]. The other researcher had setting the age parameter by group them into younger and older category. The authors had set the claimants' age below 45 years old as younger and above 45 years old as older and the authors also had stated that the claims are high for younger worker [6, 16].

3.3. Total Direct Cost Claimants on Chronic MSD Related to Types Industry, Causes Injury, Types Injury and Body Part

The claims for types industry were total up to 23 types of industry including manufacturing sectors, administration, services, civil ,farming, education and others industry. Most of the total direct cost claims were from manufacturing industry accounted RM 5,181,282.34 and accumulated near to 50% from overall cost other than others industry. In the manufacturing industry, male workers compensate approximate total direct cost RM 4,455,094.00 and female worker were costing RM 726,188.27. The average total direct cost claims for manufacturing most frequently at age 35-44 (RM 31,453.3) which is 25.5% from the others age categories. The others types industry shows a digit percentage in its distribution of total direct cost. The least of total direct cost were from supporting services to water transport industry (RM 33,842.90).All claimants from the types of industry have been summarized in Table 3.

Table 3. Total Direct Cost Based on Types Industry

Types of Industry	Total Direct Cost		
	n	Sum	%
Manufacturing	185	5,181,282.34	47.0
other services	29	988,636.54	9.0
Iron and Steel Basic industries	36	865,306.98	7.8
Personal services	33	804,805.87	7.3

The cost of MSDs is different through sectors and profession. Manufacturing is most favorite parameter used by researcher because many claimants contribute high cost on manufacturing industry. There is a study in Malaysia reported the manufacturing industry was leading on claimants between the range 2001- 2006 [1]. This is similar to the others study reported manufacturing was frequent claims [4, 9]. Manufacturing industry is a sector that produces or manufacture electrical and electronic products; chemicals, chemical products and petroleum products; wood and wood products; textiles, apparel and footwear; construction-related materials; transport equipment; and food products, beverages and others products. Manufacturing involves of mass scale and require the worker to stand and sitting for prolong hour and need to over time in time to fulfill the production target. Besides, the manufacturing sector is envisaged to expand, spurred by robust domestic demand and export-oriented industries.

Table 4 shows the type causes of injury being reported and classified by SOCSO over the periods. From the analyze, strenuous movements recorded as most frequent claims with cost RM 7,088,839.51 with similar to 64.3% and 264 claimants highest compare to overexertion in lifting objects (59), others type of accident, over exertion in pushing or pulling objects (19), Striking against stationary objects (26) and others causes of accidents were listed in the Table 4. The strenuous movement was most occurrence at age 35-44 years with average cost RM 29,833.86. Overexertion in lifting objects and other types of the accident were recorded at age 35-44 as highest average total direct cost compares to another age category. Contrast to over-exertion in pushing or pulling object was most frequent at age 25-34 years old.

Most frequent types of injury experience on sprain and strain nearly to 80% claims of total direct cost. The cost incurred for sprain and strain was RM 8,753,975.13. Dislocation reported as the highest second place of claimable claims which incurred the total direct cost of RM 665,204.98, followed by a concussion and other internal injuries RM 653,374.58. The least cost for total direct cost was multiple injuries of different nature that cost RM 74,808.93 (7%). The total direct cost for cause injury was distributed in Table 5. The most claimants on average total direct cost for sprain and strain were at age 35-44 years old (RM 28,086.39).A dislocation also incurred an average total direct cost at age 35-44 years old (RM 36,577.49). For concussions and other internal injuries, the average total of direct cost was recorded RM 50,939.32 at age 25-34.

Sprain and strain consequent to strenuous movement and the claims similarly high. Research on American Journal of Industrial Medicine 1989 reported that strain was the frequent claim and dislocation is about 31.9% of the total claimant followed by cuts, lacerations, punctures, scratches, and abrasions which was 14.9%, and chemical burns was 13.4%.11 73% on sprain and strain claims was recorded in Ohio and was the most frequent claim [9]. Similarly other research reported 35% claim was due to sprain and strain pain [5].

Sprain is a stretch or tear of a ligament, a strong band of connective tissue that connect the end of one bone with another. Meanwhile, a strain is an injury to a muscle or tendons. Tendons are fibrous cords of tissue that attach muscles to the bone. Strains often occur in foot, leg (typically the hamstring) or back. Strain is

more likely a simple stretch in the muscle or tendon compare to sprain. The symptom of strain includes the feel of pain, muscle spasm, muscle weakness, swelling, inflammation and cramping. Typically, sprain and strain pain limit the claimants to perform their daily job efficiently. Thus, this limit is reducing the productivity of workers and consequently it will reduce the number of Malaysian Gross Domestic Product in order to fulfill domestic and international demands.

Table 4 Total Direct Cost for Causes of Injury

Causes of Injury	Total Direct Cost		
	n	Sum	%
Strenuous movements	264	7,088,839.51	64.3
Over-exertion in lifting objects	59	1,542,937.56	14
Other types of accident, not classified	20	529,602.02	5.4
Over-exertion in pushing or pulling objects	19	590,446.88	5.2
Striking against stationary objects	26	574,142.82	4.8
Over-exertion in handling or throwing objects	11	357,671.00	3.2
Caught between a stationary object and a moving object	9	186,988.81	1.7
Accidents not classified for lack of data	3	57,458.40	0.5
Falls of persons on the same level	2	28,414.89	0.3
Struck by moving objects, excl. falling object	1	26,254.41	0.2
Striking against moving objects	1	21,613.80	0.2
Falls of persons from heights and into depths	1	19,045.15	0.2
Total	416	11,023,415.25	100

Table 5 Total Direct Cost for Types of Injury

Types of injury	Total direct cost		
	Count	Sum	%
Sprains and strains	335	8,753,975.13	79.4
Dislocations	20	665,204.98	6
Concussions and other internal injuries	25	653,374.58	5.9
Contusions and crushing	11	302,051.76	2.7
Other wounds	8	207,687.22	1.9
Other and unspecified injuries	5	137,598.08	1.2
Effects of weather, exposure"	3	117,070.52	1.1
Fractures	5	111,644.05	1
Multiple injuries of different nature	4	74,808.93	0.7
Total	416	11,023,415.25	100

In Table 6, back shows the highest total direct cost with RM 5,526,590.69, with the half percent of claims. Hip incurred about 40% on total direct cost (RM 4,447,674.63) follow by abdomen (RM 269,894.88), shoulder (RM 202,493.48), knee (RM 141,679.05), trunk ,multiple location (RM 99,965.29), hand (except fingers alone) (RM 72,697.32), fingers (RM 53,554.42), neck (RM 50,277.99), wrist (RM 41,612.15), and least total direct cost was at elbow (RM 7,434.10). Back and hip recorded the average total direct cost at age 35-44 respectively. Meanwhile abdomen recorded the total average cost at age 25-34.

Other researchers have specified the specific part of the body's back region as the lumbar spine or lower back and this body part records most frequent MSD claims [3, 9, 16, 17]. According to Murphy and Courtney lumbar spine pain was the main contributor reported in many industries and represent 25% of the cost claims [18]. In this data were not provided the specific of the body part on back pain. It probably includes all of the lower back pain and upper back pain. Back pain is definitely a common pain for the both industry and developed countries, with up to 50 percent of claimants suffering over the period year of 2009 until 2014. Back pain lead to disability adjusted life years and major of absenteeism [19].

Table 6 Total Direct Cost for Body Part

Body Part	Total Direct Cost		
	n	Sum	%
Back	209	5,526,590.69	50.1
Hip	152	4,447,674.63	40.3
Abdomen	9	269,894.88	2.4

Ankle	1	16,516.76	0.1
Trunk and one or more limbs	1	9,145.08	0.1
Elbow	2	7,434.10	0.1
Total	416	11,023,415.25	100

4. Conclusion

Occupational morbidity imposes major health and economic burden on individual workers, employers, and society. The SOCSO database provided the statistical data of occupational disease based on standardizing reporting. From the analyzing of the data, the chronic MSDs was determined. MSD total direct cost was reported to be amount of RM 11 billion for the five-year period, from 2009 till 2014, for the 416 claimants. This tremendous cost will greatly affect the social economy. This cost incurred shows that there is a need to concern on MSDs disease from the bottom line to the top level.

Acknowledgement

This paper is a collaboration between UTM and National Institute Occupational Health and Safety (NIOSH). Many thanks to NIOSH, especially to Ergonomic Excellence Centre for the opportunities in the joint venture and financial support through the making of this paper. In addition, I would like to express my appreciation to SOCSO for the kind cooperation in giving the data related especially on cost needs.
