

PHOTOCATALYTIC BIREFORMING OF METHANE OVER SILVER-
LANTHANUM MODIFIED GRAPHITIC CARBON NITRIDE WITH TITANIA
NANOCOMPOSITE IN MONOLITH PHOTOREACTOR

BEENISH TAHIR

A thesis submitted in fulfilment of the
requirements for the award of the degree of
Doctor of Philosophy

School of Chemical and Energy Engineering
Faculty of Engineering
Universiti Teknologi Malaysia

APRIL 2019

This thesis is dedicated to my father, who taught me that the best kind of knowledge to have is that which is learned for its own sake. It is also dedicated to my mother, who taught me that even the largest task can be accomplished if it is done one step at a time.

ACKNOWLEDGEMENT

In the name of **Allah Almighty**, the lord of the world, the most Merciful, the most Compassionate who gives me such a power, knowledge and ability to accomplish my goal.

First and foremost, I wish to express my sincere appreciation to my supervisor Prof. Ir. Dr. Nor Aishah Saidina Amin for her encouragement, guidance, critics, friendship and most of all the patience through thick and thin of my study. Without her continued support and interest, this thesis would not have been the same as presented here. I also gratitude to School of Chemical and Energy Engineering (SCEE) Universiti Teknologi Malaysia (UTM) for providing an opportunity to complete this work. I am very thankful to my husband Dr. Muhammad Tahir for his continuous support and motivation, whenever, I was in trouble and despairing.

My fellow postgraduate students at Chemical Reaction Engineering Group (CREG) should also be recognised for their support and encouragement throught the course of this study. My sincere appreciation also extends to all my friends in UTM and others who have provided motivations at various occasions.

Last but not least, I obliged my Mother for her unconditional love and prayers throughout my entire life and particularly through pursuing my doctoral endeavours. I have no words to thank my Father (late) for his motivation and support to achieve this final goal. I am also thankful to my sister Kainat Baqir (Late) and Brothers Jehazaib Baqir and Shahzaib Baqir for their lover for me. I have special love for my sons Muhammad Ibrahim and Muhammad Ahmad who suffered during this period.

ABSTRACT

Photocatalytic conversion of carbon dioxide (CO₂) and methane (CH₄) offers a solution of greenhouse gas mitigation with alternative energy supply. The objective of this study is to design and fabricate photoreactor system and to synthesize silver (Ag) and lanthanum (La) modified protonated carbon nitride (pCN) coupled titanium dioxide (TiO₂) photocatalysts for enhanced photocatalytic CO₂ reduction with CH₄ in the presence of water to fuels. The ternary Ag-La/pCN-TiO₂ composite catalysts were synthesized through sonicated assisted hydrothermal and sol-gel methods. The performance of nanomaterials was investigated using photocatalytic reforming of methane (BRM), dry reforming of methane (DRM), steam reforming of methane and steam reforming of carbon dioxide in a fixed-bed and monolith photoreactors under UV and visible light irradiations. Ag/La-loaded protonated carbon nitride nanotubes (pCNNT) produced both carbon monoxide (486 μmol g-cat⁻¹ h⁻¹) and hydrogen (79 μmol g-cat⁻¹ h⁻¹) under visible light irradiations, while productivity was highest in BRM process, which was further improved in a monolith photoreactor with CO and H₂ production rate of 770 and 891 μmol g-cat⁻¹ h⁻¹, respectively. Furthermore, using pCN-TiO₂ composite loaded with La, higher amount of CO was obtained, while production of H₂ had increased with Ag-loading. More importantly, a remarkable improvement in productivity of both CO and H₂ with H₂/CO ratio greater than one was obtained using Ag-La co-loaded pCN-TiO₂ composite catalyst. The highest CO and H₂ production rate of 2105 and 2387 μmol g-cat⁻¹ h⁻¹, respectively, were obtained using BRM process in a monolith photoreactor. The performance of monolith photoreactor was 1.4 and 3.2 fold higher for CO and H₂ rich synthesis gas (syngas) production than using fixed-bed reactor over the composite catalyst under UV-light irradiations. The reaction mechanism based on Z-scheme system for DRM and BRM was successfully developed under UV light irradiation, while direct electron transfer was observed under visible light irradiations. The quantum efficiency of 4.07 % and 4.624 % was achieved for CO and H₂ production, respectively in a monolith photoreactor, while it was only 1.144 % and 0.548 % in a fixed-bed photoreactor during BRM under UV-light irradiations. Among the operating parameters, feed ratio was the influential parameter to maximize yield and selectivity. The stability test revealed prolonged life and reusability of Ag-La/pCN-TiO₂ composite photocatalyst in three cyclic runs. The Langmuir-Hinshelwood model confirms surface reactions due to efficient sorption process in a monolith photoreactor over composite catalysts. In conclusion, Ag-La loaded pCN-TiO₂ composite catalyst and monolith photoreactor via BRM provided an ideal system to get hydrogen enrich syngas production for renewable fuels productions.

ABSTRAK

Penukaran fotobermangkin karbon dioksida (CO_2) dan metana (CH_4) menawarkan penyelesaian pengurangan gas rumah hijau dengan bekal tenaga alternatif. Objektif kajian ini adalah untuk merekabentuk dan menghasilkan sistem fotoreaktor dan untuk mensintesis fotomangkin karbon nitrida berproton (pCN) gandingan titanium dioksida (TiO_2) terubahsuai dengan perak (Ag) dan lantanum (La) untuk meningkatkan penurunan CO_2 fotobermangkin dengan CH_4 dalam kehadiran air kepada bahan api. Pemangkin komposit ketiga Ag-La/pCN- TiO_2 disintesis melalui kaedah hidrotermal dan sol-gel dibantu dengan sonikasi. Prestasi nanobahan dikaji dengan menggunakan dwipengubahan fotomangkin metana (BRM), pengubahan kering metana (DRM), pengubahan wap metana dan pengubahan wap karbon dioksida dalam fotoreaktor lapisan tetap dan monolit di bawah penyinaran cahaya UV dan nampak. Nanotub karbon nitrida berproton termuat Ag/La (pCNNT) menghasilkan kedua-dua karbon monoksida ($486 \mu\text{mol g-cat}^{-1} \text{h}^{-1}$) dan hidrogen ($79 \mu\text{mol g-cat}^{-1} \text{h}^{-1}$) di bawah penyinaran cahaya nampak, sementara produktiviti tertinggi dalam proses BRM, yang bertambah baik dalam fotoreaktor monolit dengan kadar penghasilan CO dan H_2 masing-masing sebanyak 770 dan $891 \mu\text{mol g-cat}^{-1} \text{h}^{-1}$. Selain itu, dengan menggunakan komposit pCN- TiO_2 termuat dengan La, jumlah CO yang lebih tinggi diperolehi, manakala penghasilan H_2 meningkat dengan pemuatan Ag. Lebih penting lagi, peningkatan produktiviti kedua-dua CO dan H_2 dengan nisbah H_2/CO lebih besar daripada satu diperolehi dengan menggunakan pemangkin komposit pCN- TiO_2 yang dimuatkan bersama Ag-La. Kadar penghasilan CO dan H_2 tertinggi masing-masing sebanyak 2105 dan $2387 \mu\text{mol g-cat}^{-1} \text{h}^{-1}$ diperolehi dengan menggunakan proses BRM dalam fotoreaktor monolit. Prestasi fotoreaktor monolit adalah 1.4 dan 3.2 kali ganda lebih tinggi bagi penghasilan gas sintesis yang kaya dengan CO dan H_2 (singas) berbanding dengan menggunakan reaktor lapisan tetap terhadap mangkin komposit di bawah penyinaran cahaya UV. Mekanisme tindak balas berasaskan sistem skema Z untuk DRM dan BRM berjaya dibangunkan di bawah penyinaran cahaya UV, manakala pemindahan elektron langsung diperhatikan di bawah penyinaran cahaya nampak. Kecekapan kuantum 4.07% dan 4.624% dicapai untuk pengeluaran CO dan H_2 , masing-masing di dalam fotoreaktor monolit, manakala hanya 1.144% dan 0.548% di dalam fotoreaktor lapisan tetap semasa BRM di bawah penyinaran cahaya UV. Antara parameter operasi, nisbah suapan adalah parameter berpengaruh untuk memaksimumkan hasil dan kepemilihan. Ujian kestabilan menunjukkan hayat berpanjangan dan kebolehgunaan semula fotomangkin komposit Ag-La/pCN- TiO_2 dalam tiga kitaran larian. Model Langmuir-Hinshelwood mengesahkan tindak balas permukaan disebabkan oleh proses penyerapan yang cekap di dalam fotoreaktor monolit melalui mangkin komposit. Kesimpulannya, mangkin komposit pCN- TiO_2 yang dimuatkan Ag-La dan fotoreaktor monolit melalui BRM menyediakan sistem yang ideal untuk mendapatkan singas diperkaya hidrogen untuk penghasilan bahan api yang boleh diperbaharu.

CHAPTER 1

INTRODUCTION

1.1 Background Overview

Global warming effects due to greenhouse gases, primarily carbon dioxide (CO₂) and methane (CH₄) emitted due to fossil fuel combustion and human activities are prevalent [1]. The emission reduction of CO₂ for cleaner environment can be categorized into three routes which include direct reduction of CO₂ emission from the source [2], CO₂ capture and storage (CCS) and utilization of CO₂. The direct CO₂ emission at the source can be reduced using renewable energy resources that produces lesser CO₂ [3], but these energy sources are limited compared to fossil fuels [4]. CO₂ capture and storage is a technology that is being developed to allow CO₂ emissions from fossil fuel, capture at large point sources to be transported to safe geological storage, rather than being emitted to the atmosphere [5]. CCS disadvantage is the extra cost to transport and injection to the geological storage. Besides, due to industrialization integrated with daily human activities caused the increase of fossil fuels combustion; thus mitigating CO₂ emission and/or storage for sustainable development is unachievable [6]. Therefore, utilization of CO₂ to produce chemicals and fuels is the growing concern in recent years [7].

Among the available CO₂ utilization approaches, the most widely employed technologies are thermal and plasma processes. In thermal process, CO₂ can be converted through an endothermic process by providing an input energy at elevated temperature. However, higher temperature makes this process expensive and has adverse effect on the catalyst stability, while coke produced ultimately deactivates the catalyst [8]. On the other hand, plasma technology for dry reforming of methane is considered better alternatives compared to thermal process. The plasma reforming has advantages of high conversion because reactions are conducted by electron induced chemistry. However, production of large amounts of coke during dry reforming of

methane in plasma reactor is a great challenge. In addition, higher input energy is required to generate plasma, which make this process un-economical [9-11].

In recent innovations, phototechnology has gained much attention because it works in the presence of light irradiations. Using photocatalysis, CO₂ reforming of CH₄ would be possible at normal temperature and atmospheric pressure [12]. The requirement of input energy as like endothermic process can be provided through harvesting solar energy. More importantly, catalyst can be used with prolonged stability due to mild operating conditions, while economical production of chemicals and fuels.

1.2 Photocatalytic CO₂ Reforming of CH₄

Photocatalytic reduction of CO₂ seems a potential technology to produce chemicals and fuels at normal operating conditions with the help of light irradiations. During the past three decades, photocatalytic reduction of CO₂ over various semiconductor materials has been investigated by many researchers and products reported were carbon monoxide (CO), methane (CH₄), methanol (CH₃OH), formic acid (HCOOH) and acetic acid (CH₃COOH) as discussed in Equations (1.1) to (1.5) [13-16].

Since 1980s, water as a reductant for the reduction of CO₂ in a gas phase and slurry system, has attracted considerable interest with diversity of products (e.g., CO,

CH₄, H₂, CH₃OH, HCOOH and HCHO) [13-16]. Using gas phase system, CO₂ with water can be converted to CO, CH₄ and CH₃OH as the potential products. However, slurry system promoted the production of CH₃OH, HCHO and CHOOH during CO₂ reduction with H₂O [17]. In this perspective, production of CH₄ from photo-reduction of CO₂ with water vapours over Fe/TiO₂ [18], photo-reduction of CO₂ with H₂O to liquid products (CH₃OH, HCHO) over CeO/TiO₂ [19], use of Ag-MgO/TiO₂ for the production of CH₄ from CO₂ and water in gas phase system [20], Fe-doped CeO for CO and CH₄ production from CO₂ and water vapours [21], production of CO from CO₂-water vapours over Ag/CdS [22], Ag/TiO₂ nanorods [23], g-C₃N₄/Ag/TiO₂ composite catalyst for the production of CO and CH₄ from CO₂-water [24], production of CO from CO₂-water using g-C₃N₄/N/TiO₂ catalyst [25] and g-C₃N₄/Cu/TiO₂ for the production of CH₃OH, HCHO and HCOOH from CO₂ in slurry system [26], have been reported.

Although, different types of photocatalysts with appreciable improvement in CO₂ reduction to fuels has been succeeded by numerous researchers, but main challenge is diversity of products distribution. In addition, research on utilization of both greenhouse gases (CO₂ and CH₄) is still relevant. CH₄ is emitting from gas supply chain [27], landfill [28] and industries, is a severe challenge for the future. Therefore, recycling both greenhouse gases (CO₂ and CH₄) to valuable chemicals and fuels by reforming deems an attractive pathway for a cleaner environment. CO₂ reforming is a method of producing synthesis gas (syngas), a mixture of CO and H₂, from the mixture of CO₂ and hydrocarbons, in particular, methane. Conventionally, syngas is produced via dry reforming of methane. The reforming of CO₂ and CH₄ is a challenging task as both are stable molecules, while reforming of these two molecules to syngas is an endothermic process that demands excessive supply of energy [29, 30]. However, it is a main raw material in the production of liquid fuels. Besides, syngas (H₂/CO) ratio for the production of liquid fuels has great importance, e.g., a ratio of H₂/CO of 2 would be required in methanol synthesis process.

Methane can be converted into syngas through different reforming technologies such as steam reforming of methane (SRM) as shown in Equation (1.6). CO₂ can also be utilized with CH₄ for the production of syngas through catalytic CO₂

and CH₄ reforming or dry reforming of methane (DRM) as explained in Equation (1.7) [31]. DRM offers advantages such as mitigating both greenhouse gases, and direct production of syngas [32]. However, DRM operates under higher temperature via thermal reforming is prone to coking and reduces catalyst stability [33].

Combination of SRM and DRM also known as bireforming of methane (BRM) could be a promising approach and interesting pathway for the production of H₂ enriched syngas as explained in Equation (1.8) [34]. BRM has advantage over SRM and DRM for producing hydrogen with a stoichiometric H₂/CO ratio of 2, a more favourable composition for the production of liquid fuels via Fischer-Tropsch Synthesis (FTS) [35]. Although, BRM is an attractive approach compared to DRM, yet it also requires larger input energy due to endothermic process [36].

With the help of phototechnology, reforming processes can be conducted at normal temperature and atmospheric pressure. However, there are limited reports available on photocatalytic CO₂ reduction with CH₄ through phototechnology. Recently, photocatalytic CO₂ reforming of CH₄ to fuels over different semiconductor photocatalysts has been reported [37, 38]. In one of the earlier studies, Shi et al. [39] reported photocatalytic CO₂ reduction with CH₄ over Cu/CdS modified TiO₂/SiO₂ photocatalyst in a fixed-bed photoreactor operating at high temperature. Products obtained were C₂H₆, CH₃COOH, CH₃COCH₃ and CO. ZrO₂ photocatalyst was employed for CO₂-CH₄ reduction under UV-light with the production of CO and H₂

as the main products [40]. Similarly, CO and H₂ were produced during CO₂ reduction with CH₄ over Pt-loaded TiO₂ and Au/Rh loaded TNTs catalyst, respectively [41]. However, literature on photocatalytic CO₂ reduction with CH₄ in the presence of H₂O via BRM is not available. Besides, ubiquitous TiO₂ is mainly employed as a photocatalyst in CO₂ reforming of CH₄, but the production rate was not much appreciable. Lower TiO₂ photoactivity attributing to poor CO₂ adsorption due to acid nature and fast photogenerated charges recombination rate.

Significant research has been conducted on developing efficient photocatalysts, while the use of basic oxide in TiO₂ is considered as one prospect to promote CO₂ adsorption. In recent years, rare-earth metals are typically investigated for the modification of TiO₂ structure to enable the increment of surface oxygen vacancies [42]. Lanthanum (La), due to the unique electronic configuration and spectral characteristics, is considered as the best dopant for modifying crystal structure, optical properties and surface adsorption of TiO₂ [43, 44]. Li et al., [45] reported the use of La as an efficient metal for selective photocatalytic CO₂ reduction with H₂O to CH₄ under UV-light. The enhanced and selective photoactivity of La/TiO₂ photocatalyst was due to higher CO₂ adsorption because of its surface basicity with proficient charge separation. Similarly, silver (Ag) metal is gaining large interest due to its appropriate work function (W_s) for photocatalytic applications [46, 47]. Many research articles reported the use of Ag based semiconductors for selective CO₂ photoreduction during photocatalytic CO₂ reduction with H₂O under UV and visible light irradiations [48-52].

Recently, graphitic carbon nitride (g-C₃N₄) semiconductor is considered very promising for CO₂ reduction applications. This is because of its merits of low-cost preparation, high chemical stability and possessing appropriate electronic structure with medium band gap energy (2.70 eV) [53, 54]. Nevertheless, photoactivity of the pure g-C₃N₄ is still limited due to fast charges recombination rate [55]. Many attempts have been employed to increase the performance of g-C₃N₄ such as surface charge modification, designating an appropriate textural porosity, metal doping, non-metal doping and coupling with other semiconductors [26, 56]. Ong and co-workers reported the surface charge modification of g-C₃N₄ via protonation with enhanced photo-

activity for CO₂ reduction to CH₄ [57]. In another work, g-C₃N₄ loaded with Pt for enhanced CH₄ production during photocatalytic CO₂ reduction has been reported [58]. CeO₂ loaded into g-C₃N₄ remarkably enhanced photocatalytic activity for CO₂ reduction by H₂O to CO and CH₄ [59]. Similarly, Ag-loaded-gC₃N₄ has been investigated for selective H₂ production as Ag suppressed the recombination of charge carriers [49, 60].

In the recent development, fabrication of semiconductors heterojunctions or Z-scheme photo-catalysts are considering more significant due to efficient charges separation with the adjustment of band structure for selective CO₂ reduction to fuels. In this perspective, CO₂ photoreduction with H₂O to CH₃OH was tested using g-C₃N₄/Cu/TiO₂ as a photo-catalyst [26]. In another work, indirect Z-scheme BiOI/g-C₃N₄ was investigated for visible light driven CO₂ reduction with H₂O with the production of CO, H₂ and CH₄ [61]. The selective photocatalytic CO₂ reduction with H₂O over g-C₃N₄-N/TiO₂ [62], ZnV₂O₆/g-C₃N₄ [63] and Mg-gC₃N₄ [64] composites have been investigated. Similarly, Ag-loaded g-C₃N₄/TiO₂ for CO₂ photo-reduction by H₂O to fuels was explored [24]. g-C₃N₄ is widely investigated in photocatalytic CO₂ reduction with H₂O, but not for CO₂-CH₄ reaction system via DRM and BRM. The efficiency of g-C₃N₄ can be further improved through surface charge modification via protonation [63]. Besides, development of Ag/La modified Z-scheme g-C₃N₄/TiO₂ composite would be promising for enhanced photocatalytic dry and bireforming of methane.

Upscaling CO₂ reforming of CH₄ system to synthesis gas (CO and H₂) requires stringent criteria for designing the photoreactor system. The choice of reactor is critical since it affects the overall CO₂ reduction efficiency and products selectivity. Almost all photoinduced CO₂-methane reaction systems were conducted in a fixed-bed photoreactor, where catalysts are distributed over the reactor surface. The fixed-bed reactors have limitations: (1) poor light utilization efficiency due to less exposed active surface area; (2) lower adsorption- desorption process due to less contact of gas with catalyst; (3) smaller catalyst loading and (4) less light intensity to stimulate complex nature of CO₂-CH₄ photocatalytic reaction [65]. Therefore, the design of highly

efficient photoreactor for CO₂-CH₄ reduction is crucial to scale up phototechnology from laboratory to commercial level.

More recently, the attention on immobilized photocatalytic systems with enhanced light utilization efficiency has surged [66, 67]. Among the different supports, monolithic substrates are mainly studied because of the unique structure, higher adsorption-desorption process, larger active surface area, more catalyst loading, controlled selectivity and large photonic efficiency [66, 68]. In this perspective, monolith photoreactor found very efficient for photocatalytic CO₂ reduction to CO with enhanced selectivity and yield using H₂O and H₂ reductants over different types of semiconductor materials [48, 69].

The focus of this study is to design and develop structured Ag/La modified g-C₃N₄-TiO₂ nanocomposite for photocatalytic dry and bireforming of methane in a monolith photoreactor. The coupling TiO₂ and g-C₃N₄ will be suitable for Z-scheme photocatalytic reactions under UV-light and direct heterojunction electron transfer under visible light. The modification of g-C₃N₄/TiO₂ with La/Ag metals will develop novel polymeric complexes that would maximize the process efficiency under UV and visible light irradiations. The use of water in dry reforming of methane would be suitable for the production of hydrogen enrich syngas. The monolith photoreactor will maximize the illuminated surface area even at lower light intensity, thus increasing the efficiency of reactor system for CO₂ photo-reduction to hydrogen enrich syngas. The optimization of different operating parameters and kinetic investigation will further improve the system efficiency.

1.3 Problem Statement

The conversion of greenhouse gases i.e., CH₄ and CO₂ to renewable fuels has become a challenge to achieve net-zero carbon cycle for monitoring energy crises and environment pollution. The breaking stable molecules of CH₄ and CO₂ demands higher input energy, while overcoming this barrier through external supply of energy makes

this process uneconomical. The main challenges for the conversions of greenhouses to chemicals and fuels are as follows:

1. Thermal process requires higher input energy to break stable CO₂ and CH₄ molecules. The energy barrier for recycling CO₂ and CH₄ can be resolved using phototechnology, yet limited reports are available on photocatalytic CO₂ reduction with CH₄. The lower production rate during photocatalytic conversion of CO₂ and CH₄ with diversity of products is another barrier in the use of phototechnology;
2. Among the semiconductors, TiO₂ and metal modified TiO₂ photocatalysts have been investigated for CO₂ reforming of CH₄. However, TiO₂ yielded lower photo-activity due to faster charges recombination and inappropriate redox potentials. This urges to find new and highly efficient composite photocatalyst for selectivity DRM process under UV and visible light irradiations. Recently, g-C₃N₄ has been investigated for CO₂ reduction with H₂O applications, however, it has not been reported in DRM and BRM applications;
3. The production of synthesis gas with higher H₂/CO ratio in another challenge in photocatalytic dry reforming of methane process. This is because, during photocatalytic CO₂ reduction with CH₄, diversity of products has been reported;
4. Besides, photoreactors investigated are fixed-bed which have lower quantum efficiency. These reactors are not very efficient due to inefficient light distribution and have minimum surface area for carrying catalytic reactions.

1.4 Research Hypothesis

The lower CO₂ conversion efficiency and production rates through phototechnology can be improved by employing an efficient reducing agent, photocatalyst and photoreactor. Therefore, the followings are the research hypothesis:

1. Although, both CO₂ and CH₄ are very stable molecules, yet CO₂ and CH₄ can be converted to chemicals using phototechnology. The problem of lower TiO₂ photoactivity can be resolved by loading with basic oxide materials, in particular lanthanum (La). Basic oxides would be helpful to improve CO₂ adsorption and will promote charges separation.
2. The use of graphitic carbon nitride (g-C₃N₄) would be promising in photocatalytic CO₂ reduction with CH₄ due to its visible light response, appropriate band structure and low-cost synthesis. The surface charge modification and addition of metals such as Ag and La metals would be promising to improve efficiency and selectivity for synthesis gas production;
3. Coupling g-C₃N₄ with TiO₂ will provide appropriate band structure with efficient charges separation and would enable efficient reduction of CO₂ with CH₄ under UV and visible light irradiations. For this purpose, direct heterojunction of g-C₃N₄/TiO₂ for visible light and Z-scheme g-C₃N₄/TiO₂ nanocomposites would be promising for UV-light applications. The efficiency of composite will be further improved by loading with Ag and La metals, thus would be helpful to improve photoactivity and selectivity;
4. Composition of synthesis gas can be adjusted using different reforming technologies. The lower H₂/CO ratio in synthesis gas during CO₂ reduction with CH₄ can be improved by combining DRM process with steam reforming of methane (SRM). Thus, photocatalytic CO₂ reduction with CH₄ in the presence of H₂O via bireforming of methane (BRM) would be promising to get higher production rate and selectivity;
5. The lower quantum efficiency of photoreactor system because of inefficient light distribution over the catalyst surface is intended to overcome employing monolith photoreactor. The monolith photoreactor will be productive to provide larger illuminated active surface area, higher adsorption-desorption and efficient mass transfer toward the catalyst surface. Higher light distribution and harvesting over the catalyst surface would also be possible utilizing micro-channels, ultimately stimulating higher quantum efficiency toward efficient reduction of CO₂ with CH₄/water system;

6. The effect of different parameters and their optimization would also be helpful to improve production rate and products selectivity. The kinetic study will further provide insights about the photon flux utilization and reaction rate limitations.

1.5 Research Objectives

The objectives of this research are:

- (a) To synthesize and characterize Ag/La modified g-C₃N₄-TiO₂ nanocomposite photocatalysts functional under UV and visible light irradiations;
- (b) To study the performance of composite nanocatalysts for photocatalytic CO₂ reduction with CH₄/H₂O through dry and bireforming of methane under UV and visible light irradiations;
- (c) To compare quantum performance of fixed-bed with a monolith photoreactor for photocatalytic CO₂ reduction with CH₄/H₂O through dry and bireforming of methane;
- (d) To investigate effect of process parameters on photocatalytic bireforming of methane over composite photocatalyst in a monolith photoreactor;
- (e) To optimize process parameters using response surface methodology and develop kinetic model to determine reaction rate parameters in photocatalytic bireforming of methane.

1.6 Research Scope

This study focused on determining some mechanistic and fundamental problems pertaining to lower CO₂ and CH₄ reduction efficiency and products selectivity. The fabrication of plasmonic and polymeric nanocatalysts with various metals and co-metals loading into pCN and pCN-TiO₂ nanostructures has been

inspected. The effects of operating parameters on CO₂ reduction such as metal-doping levels, feed ratios, and reaction temperature and irradiation times is also deliberated. The performance analysis of a monolith with a fixed-bed photoreactors has been investigated to get higher yield and selectivity. The reaction mechanisms of CO₂ reduction and CH₄/water oxidation and quantum efficiency analysis has been deliberated. The CO₂ reduction efficiency is related to maximize yield of desired products. Therefore, the specific research scope of this study is as follows:

1. The catalysts such as TiO₂, pCN pCN-TiO₂, Ag-La/pCNNT and Ag/La modified pCN-TiO₂ are synthesized using sol-gel and hydrothermal methods to investigate the route of CO₂ reduction with CH₄/H₂O. The optimized materials are supported over the monolith channels using sol-gel dip-coating method. The catalysts are characterized using XRD, SEM, FESEM, HRTEM, BET, XPS, UV-Visible and PL spectroscopy. This was helpful to investigate crystallinity, phase, morphology, surface area, pore size distribution, metals transition states and optical properties.
2. The performance of catalysts for photochemical reduction of CO₂ with CH₄/H₂O is investigated using photocatalytic steam reforming of methane (SRM), photocatalytic dry reforming of methane (DRM) and photocatalytic bireforming of methane (BRM) under UV and visible light irradiations. The role of each catalysts is critically evaluated to understand their impacts on the products yield and selectivity in the presence of different reforming processes and light systems.
3. The photoreactors employed are fixed bed and monolith of multiple channels. The quantum performance of both photoreactors is investigated using different reforming systems (i.e., SRM, DRM and BRM) under UV and visible light irradiations. In a fixed bed, photocatalysts are distributed at the reactor bottom, however, they are coated inside monolith microchannels using sol-gel dip-coating method. The mass flow controllers are employed to adjust feed flow rates and feed ratios in different reaction system. A reflector type 200W Hg lamp is used as a source of UV-light irradiations with intensity 150 mW/cm² and wavelength 254 nm. A solar simulator is used as a source of visible light

irradiations with intensity equal to 100 mW/cm^2 . More importantly, solar arrays with batteries are installed to provide input electricity for the operation of both photoreactors.

4. The operating parameters investigated are reaction temperature, feed ratios, and monolith geometry and irradiation time. The reaction mechanism is developed to find out key parameters in CO_2 reduction applications for different reforming systems under UV and visible light irradiations.
5. The optimization of process parameters is carried out using response surface methodology (RSM). The kinetic model is developed using Langmuir-Hinshelwood mechanism and rate constants are determined.

1.7 Research Significance

Greenhouse gas CO_2 is efficiently reduced with CH_4 for synthesis gas (CO , H_2) production in the presence of different photo-catalytic systems. The monolith photoreactor performance is very encouraging while the efficiency found was much higher compared to fixed-bed photoreactor. The composite catalysts are highly productive for CO_2 and CH_4 reduction to syngas gas. The several outcomes of this research are described below:

- (a) A new route for photocatalytic CO_2 reduction with CH_4 through dry reforming of methane (DRM) and bireforming of methane (BRM) reactions.
- (b) Development of microchannel monolith photoreactor system to investigate efficient photocatalytic DRM and BRM for synthesis gas production.
- (c) New methods and findings on the synthesis of protonated graphitic carbon nitrides nanotubes and z-scheme composite catalysts.
- (d) Low-carbon economy shift through CO_2 recycling.
- (e) Alternative solutions to energy crises and global warming.

1.8 Layout of Thesis

The research is focused on the photocatalytic CO₂ reduction with CH₄ through dry reforming of methane and biforming of methane over Ag or La doped and Ag-La co-doped pCN-TiO₂ composite nanocatalyst in a fixed-bed and continuous mode operation of monolith photoreactor. The development of Ag-La modified pCN-TiO₂ nanocatalyst suitable for efficient CO₂ reduction via DM and BRM with H₂/CO and hydrocarbon fuels has been investigated. The synthesis and characterization of materials, optimization of metals loading, investigation of operating parameters, and evaluation of reactor performances for higher production rate and reaction mechanisms are discussed in different chapters. This thesis consists of eight chapters.

Background of the research and problem at hand, research hypothesis, objectives and scope of this study are discussed in Chapter 1. Chapter 2 presents literature survey pertaining to possible pathways for CO₂ recycling, fundamentals and progress in CO₂ reduction to hydrocarbon fuels, progress in CO₂ reduction with CH₄ over different photo-catalysts, selection of photo-catalysts, and description of photocatalytic reactors. In Chapter 3, general description of research methodology and detailed experimental strategies are discussed. The characterizations of nanocatalysts are discussed in Chapter 4. Performance analysis of metals modified TiO₂ and pCN in a fixed-bed and monolith photoreactor for photocatalytic CO₂ reduction with CH₄/H₂O is presented in Chapter 5. Chapter 6 investigates the photocatalytic CO₂ reduction via BRM over Ag-La modified pCN-TiO₂ catalysts in a microchannel monolith photoreactor under UV-light irradiations. The optimization of process parameters using response surface methodology and kinetic model development has been presented in Chapter 7. Finally, Chapter 8 contains the overall conclusions of this study and recommendations for future work.
